

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 80001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere, and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted. Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field, interdisciplinary topics, science policy, and administration, or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally

not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The title should be brief, specific, and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references:

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355-362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319-322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

The language of DNA: How to understand what a sequence tells you about itself

Reduced to its elementary building blocks, a piece of English text is just a 'character string' – a chain of 50-odd symbols (alphabets, digits, punctuation marks, etc.) arranged in a sequence, some symbols occurring more often than others. A sonnet by Shakespeare, a railway timetable, a common minimum programme of the government, announcements of the Nobel prizes and editorials in *Current Science* are all character strings. However, despite their widely differing contents and styles, even a casual look at them is enough to make out what they tell you.

DNA, the hereditary material, is also a collection of (simpler) character strings, made up of just the four symbols A, T, G and C. The DNA sequences also differ greatly in their 'messages'; some 'code' for proteins, others for nucleic acids, still others promote the manufacture of their own copies, while yet another set prevents the copying process. Unlike English prose, however, a casual (or even a thoroughly and painstakingly non-casual) glance is *not* enough to tell us as to which of these (or other) categories does a given DNA sequence belong. And we do need such information, the need becoming more and more pressing as the days go by. The charge of the light brigade on human and other genomes continues to generate DNA sequences at increasingly faster rates. Ironically, almost 90% of the DNA, at least in higher organisms, performs no *known* function (and is therefore crudely called 'junk DNA'). To put to use the sequence data, obtained at enormous expense, it is

essential to have the means to identify whether a sequence at hand is junk or functional, and if functional, to guess its likely role.

S. Tiwari *et al.* review (page 12) the different methods used for making sense of DNA sequences. In principle, the approaches are no different from what we use (mostly subconsciously) to distinguish between, say, Maugham and Hemingway; most authors have a characteristic 'style' which we learn to recognize after reading them for a while. The DNA sequences (coding regions, promoters, enhancers and the like) too have their characteristic 'signatures', which can become apparent if we have a number of examples of each of the categories. However, these are not readily apparent to the human senses, (well, not quite; there are reports of DNA sequences being set to music and the connoisseurs claiming to be able to distinguish between a Beethoven-like protein region from the cacophony of a noncoding one!), and computers have to be brought in. A variety of mathematical and statistical techniques have to be used to make this process of pattern-recognition automated, objective and rigorous. Ramaswamy and colleagues describe many of these (including the ones developed by them) in detail, and also point out the criteria (sensitivity, specificity, etc.) of judging the relative merits of these approaches. Like all vibrantly active fields, there has been considerable progress in the recent past, and there is considerable scope for more improvement. This is one (and perhaps the only) area of modern molecular biology where the physicists/mathematicians/computer scientists, with their (indisputably) infinite ignorance and (arguably) unlimited intelligence,

may manage to make really important contributions.

N. V. Joshi

Seeing is believing: Examining the dinucleotide frequencies in a DNA sequence

The simplest descriptors of the composition of a DNA sequence are the proportions of the four bases A, T, G and C. Logically, the next set of descriptors are the proportions of the sixteen possible dinucleotide pairs; and sequences having the same composition of the four bases can differ markedly from each other when the sixteen proportions are compared. Knowing the extent and nature of such differences is of interest to the sequence analysts. The self-evident and simplest way of doing it is to compare the sixteen proportions of the first sequence with the corresponding ones of the second – sixteen pairs of thirty-two numbers. This, however, poses a major problem. Most biologists (from the lowly taxonomists to the super-elite biotechnologists) are extremely reluctant to reduce their finding to a mere set of numbers, and even more reluctant to look at others' findings when expressed as numbers.

If all you want to do is to describe, then a picture can do the job much better – something well known for centuries. To illustrate with an unrelated example, one can more easily see the differences in the pattern of variation of rainfall throughout the year between say Calcutta and Bangalore, by looking at their mean monthly rainfall profiles. An ingen-

ious variation of this theme is adopted by A. Pan *et al.* (page 50). Instead of the usual *X* and *Y*-axes in a plane, they use sixteen axes, represented as arrows beginning at the origin, with an angle of 360/16 degrees between the neighbouring arrows. These axes now represent the sixteen nucleotide pairs, and the proportion (of AA, AT, ..., etc.) found in any sequence can be marked off along the axis (arrow) corresponding to that nucleotide pair. A closed sixteen-sided polygon, formed by successively joining the points marked on adjacent axes, (or a 'map', which the authors mystifyingly call a contour diagram) shows all the sixteen proportions simultaneously. Two or more different sequences can now be compared with just a single glance at the colourful, glowing com-

puter screen. The shapes of these polygons display the same information as contained in the sixteen pairs of numbers, but the eye, evolved over millions of years for instantly interpreting complex patterns, seems to be able to extract some meaning out of it.

It has not escaped the authors' attention that this could be generalized to examine trinucleotide frequencies and similar other features. They are also aware of the large number of different ways in which the sixteen dinucleotides could be assigned to the sixteen directions, and after some experimentation, have settled on one which gives aesthetically more appealing patterns. They do not mention a linear diagram, however, and it is entirely possible that someone else would, justifiably

claiming that such a subtle change produces profound differences in the displayed patterns.

After the descriptions, follow the inferences, and the authors describe how the maps for plant, parasite and random sequences show *significantly* different dinucleotide proportions. When you have pretty pictures to convince you, why worry about such mundane technicalities as statistical tests? The appealing combination of molecular biology and computer graphics is far more persuasive than a feeble statistical phrase like 'significantly different, $p < 0.05$ '. After all, it is the performance of the advertising and publicity section, and *not* statistical quality control, which make or break a company.

INDIAN INSTITUTE OF SCIENCE

BANGALORE 560 012

Applications are invited from Indian nationals preferably below the age of 35 years for faculty positions at the level of Assistant Professor in the Department of Biochemistry. The candidates if selected are expected to develop and maintain independent research in any chosen area of biochemistry as well as collaborate with other faculty and contribute to teaching programme.

The candidates should have a Ph.D degree with about 3 years of postdoctoral research experience. Those who wish to develop new programmes of research in areas other than those in which they are presently working, or whose interests bridge basic and applied research are also encouraged to apply. Small start-up funds could be provided. The total emoluments at the minimum of the scale (Rs 3700-125-4950-150-5700) are around Rs 1,23,000 per annum. Interested persons should send: (1) curriculum vitae, list of publications, important reprints and name and address of three referees and (2) a brief description of the proposed research programme and the minimum facilities required for carrying it out, to Prof. M. Vijayan, Chairman, Division of Biological Sciences, Indian Institute of Science, Bangalore 560 012, India, within two months of the appearance of this advertisement. The referees may be requested to send their assessment directly to Prof. Vijayan.

CORRESPONDENCE

Herbal medicines

In a letter published recently in *Current Science* Tripathi¹ has stressed on the importance of traditional Indian medicines. In the present scenario where 80% of the world population has no access to the benefits of western medicines due to financial constraints, it is hardly necessary to emphasize the relevance of traditional remedies which constitute a major part of the health care system in the developing countries and are also entering the therapeutics in the developed countries. However, most of these drugs are derived from plant products, and a couple of discomfoting reports published recently reveal some problems associated with the use of herbal medicines (HM).

In most of the cases HM escape toxicity testing before they are marketed. Some of them contain mercury, lead, arsenic and poisonous organic substances in harmful amounts. Hepatic failure and even death following ingestion of HM have been reported². A perspective study shows that 25% of the corneal ulcers in Tanzania and 26% of the childhood blindness in Nigeria and Malawi were associated with the use of traditional eye medicines³.

Quantitative variation of the constituents may be very high from batch to batch of a plant material. For example,

paeoniflorin content of 12 samples of red peony root (*Paeonia lactiflora*, used as a traditional Chinese remedy for eczema) bought in London was found⁴ to range from 0.01% to 4.5%. This makes correct dosing of HM a difficult task.

Sometimes patients use traditional and western medicines simultaneously. The interaction of these two types of drugs *in vivo* may be dangerous. Piperine present in many Ayurvedic formulations is known to increase the toxicity of theophylline, a bronchodilator routinely used by the asthmatics and also of phenytoin, an anticonvulsant⁵.

Alarminglly HM, in some cases, are found to be admixed with allopathic medicines. In Leicester Royal Infirmary one sample of traditional Chinese medicine, given to a lady for eczema, was found to contain a steroid⁶. Several undeclared drugs including phenylbutazone, diazepam and corticosteroids were detected in a traditional Chinese cure for arthritis⁷.

Safe use of HM is a burning question at present. A project is under way at the WHO Collaborating Centre for International Drug Monitoring in Sweden to classify common toxic ingredients of HM (ref. 8). One government-funded agency in the UK and another in the US have

been appointed to investigate complaints from the consumers and to recommend removal of the harmful products from the market. With the increase in the popularity of HM throughout the world, it is necessary to ensure safety of the patients.

Global warming and forest fires in tropical Himalaya

This is in reference to the article 'Ecology of forest fires in chir pine (*Pinus roxburghii* Sarg.) forests of Garhwal Himalaya' (R. M. Semwal and J. P. Mehta, *Curr. Sci.*, 1996, 70, 426-427).

P. roxburghii indeed is one of the dominant tree species of tropical Himalaya¹. In general, tropical forests produce nearly two and ten times litter biomass compared to that in temperate and arctic

climates, respectively and are thought to have proportionate decomposition capacities under adequate moisture conditions². Higher temperature tends to deplete top soil moisture at a faster rate, and if not

CORRESPONDENCE

duly replenished, can restrict microbial activity and cause crisp dryness of litter biomass under low-humid conditions favouring forest fires.

In pine forests, needles decompose slowly due to its higher lignin content. Lignin resists microbial attack³ and is reported to accumulate in the litter, exerting a negative effect on its further degradation⁴. The leaf biomass therefore accumulates in pine forest.

The fires of summer 1995 in pine forests in western and central Himalayas is typical in enormity of magnitude and the extensive floral and avi-faunal losses it caused. The fire was reported along the broad distribution range of *P. roxburghii* from almost every district in Himachal Pradesh and various locations extending up to Garhwal Himalaya. In Himachal Pradesh, the Dharmshala Circle alone reported 226 forest fires between May to June⁵. The summer also recorded prolonged dry spell and a mean temperature rise of the order of 2–3°C above normal⁶.

The anomaly of temperature rise of 2–4°C has been widely discussed under the proposed climatic change, leading to

global warming by middle of next century⁷. Drought is one of the chief fears anticipated⁷, implying that vulnerability of pine forest to seasonal fire may increase under the situation.

CSIR Complex,
P.B. No. 6,
Palampur 176 061, India

R. L. Semwal adds:

Our studies on chir pine forests and

associated grazing lands in Garhwal Himalaya deal with the effects of forest fire on soil, phytosociology, biomass and productivity, litterfall and litter decomposition and nutrient return through litter. Based on our work and available published literature from this region, presently we are not in a position to establish any precise relationship between forest fires and global warming phenomenon. However, as has been pointed out by Vats, it is true that warming of local atmosphere takes place during severe forest fires. Thus, in-depth studies need to be conducted in this direction to explore any such relationship. Nevertheless, we ought to have a well-thought programme to fight with the wild fires in Himalayan region which incurs environmental and social losses on an unmeasurable scale.

RESEARCH NEWS

Classifying the kiwi

Kartik Shanker

Molecular genetics has, in recent years, become an invaluable tool for conservation biologists. Present thinking^{1,2} suggests that the higher the genetic variability within a species, the better are its chances for survival, and most work to date has centred around this. There has been substantial debate^{1–5} about the importance of genetics in conservation, but many ecologists⁶ still believe that population studies or behavioural studies are more useful. In the light of recent work^{2,7}, however, it seems clear enough that molecular genetics is here to stay in conservation. In a world with limited resources and an overloaded conservation schedule, tough choices have to be made as to which species, and specifically which populations, are to be conserved. These choices

would depend on our priorities and current opinion favours retention of genetic diversity^{1–5}. If we do assign priorities based on genetic diversity, we obviously need detailed studies in molecular genetics.

Baker and co-workers⁷ studied the molecular genetics of brown kiwis in New Zealand. The work is noteworthy for two reasons; firstly, they found levels of genetic differentiation between populations that had not been found in bird populations earlier. Secondly, they showed that the taxonomy of the brown kiwi needed to be reviewed and perhaps changed in the light of their study. This is important because the kiwi is an endangered bird and conservation priorities do need to be assigned.

Molecular genetics can help clarify taxonomic errors because traditional taxonomies depend on morphological characters which may not reflect true genetic distances between species². Since most work has depended on the subjective classification of taxonomists, it is likely to be riddled with errors. The case of the Camden County gopher clearly illustrates this².

In 1898, a distinct species of gopher was described in Camden County, Georgia, USA as *Geomys colonus*. The population consisted of very few individuals and was listed as endangered. However, a recent molecular genetic survey showed that this species was not genetically distinct from the more common *Geomys pinetis*, which is found all over USA. In

Table 1. Morphological characters used to classify the kiwi and the results of the allozyme and mtDNA work (from Baker *et al.*, 1995)

*Found only on little spotted kiwi; †Found only on great spotted kiwi.; ‡Numbers refer to haplotypes listed in Figure 2.

**Figure 1.** Distribution of the various populations of brown kiwis in New Zealand (from Baker *et al.*, 1995).

fact, there were wider genetic differences across different populations of *G. pinetis*. Hence, *G. colonus* did not warrant recognition as a separate species. Either a mistake had been made in the original classification or *G. colonus* had gone extinct and was replaced by the common *G. pinetis*. In either case, incorrect taxonomy led to an inappropriate conservation priority for the Camden County population of gophers.

Kiwis are small, non-flying birds, found only in New Zealand. Unfortunately, kiwi populations have been fragmented by

hunting, habitat destruction and introduced mammalian predators. They are now found in small, discrete populations that are unlikely to exchange genes. Brown kiwis are found on North Island, South Island and the smaller Stewart Island (south of South Island) (Figure 1). Initially, the North and South Island populations were recognized as separate species (*Apteryx mantelli* and *Apteryx australis*, respectively) on the basis of morphological characters. Subsequently, they were clubbed as a single species and accorded the status of subspecies (*A. australis mantelli* and *A. australis australis*). The Stewart Island population was also recognized as a subspecies (*A. australis lawryi*). Although this classification was widely accepted, reports of differences in feather lice, blood proteins and possibly calls shed some doubt on its validity (for a review, see ref. 7 and references therein). Baker *et al.*⁷ attempted to resolve the issue using molecular genetic techniques.

A number of studies in recent times have been done on maternally inherited mitochondrial DNA, because they provide an excellent source of genetic markers and can be used to reconstruct intra-specific phylogenies of matriarchal lineages⁸. Baker *et al.*⁷ examined differences in the cytochrome b gene from mitochondrial DNA. In the 60 kiwis studied, 654 bp of mtDNA was sequenced; there were 21 types of sequences due to variation at 42 sites. Based on these 21 types, the brown kiwis could be separated into five

populations – the North Island population, the Stewart Island population and three different populations on South Island. Remarkably, none of the populations shared any sequence type.

As one might expect, the North and the South Island birds were clearly divided. However, the northernmost South Island population (the Okarito population) turned out to be a sister group of the North Island population. Baker *et al.*⁷ suggest that the two sub species can now be reinstated as separate species. This is based on the result that the genetic distance between the two populations is as great as that between the two species of spotted kiwi (*A. haastii* and *A. oweni*) (Figure 2). Also, the Okarito population of the South Island can be classified as the same species as the North Island population.

The most remarkable aspect of their result, however, was the extreme structuring of the matrilineal lineages of cytochrome b, with virtually every population showing private alleles (Table 1). This is a first for mtDNA studies in vertebrates. Baker *et al.* also looked at genetic differences between populations by studying the variation in enzymes. The results from the allozyme study confirmed the results of the mtDNA work, showing levels of subdivision seen only in vertebrates such as salamanders, cave-dwelling fishes and small mammals, all animals with very poor dispersal power and disjunct populations.

Unlike small mammals, bird populations were not expected to be genetically

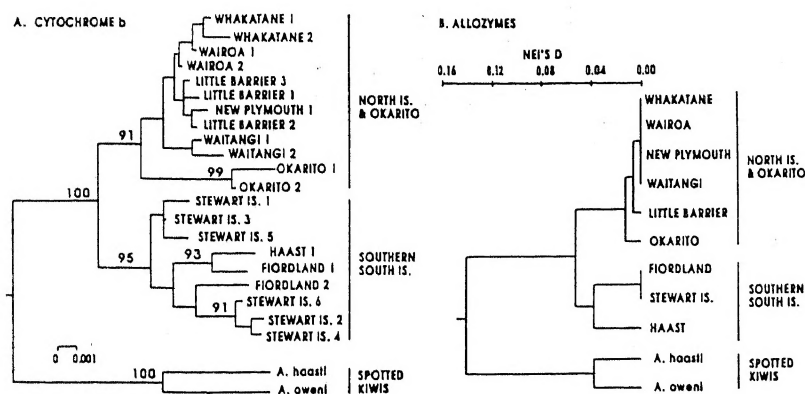

Figure 2. The mtDNA and allozyme trees constructed for the kiwi populations (from Baker *et al.*, 1995).

Figure 3. A great spotted kiwi (*Apteryx oweni*); the brown kiwi (*Apteryx australis*) is a little smaller and its body colour is a streaked dark brown and light brown. [The *Encyclopedia of Birds* (eds Perrins, C. M. and Middleton, A. L. A.), George Allen and Unwin, London, 1985.]

different from each other. Their ability to disperse (due to flight) would result in greater exchange of genes between populations and less genetic difference between populations⁹.

Kiwis, however, seem to be more like small mammals than birds (Figure 3). They are the smallest of the seven families of ratite birds. Ratites are non-flying birds that lack the keeled breastbone to which the pectoral muscles are attached. Kiwis, like other ratites, have an adult plumage that is the same in structure as the juvenile down of other birds. They live in burrows, and are essentially nocturnal. These and

other features such as hair-like feathers, facial bristles, two functional ovaries, a well-developed sense of smell and absence of flight make them more like small mammals in their ecology¹⁰.

The brown kiwis were once widely distributed in New Zealand. Range fragmentation must have accelerated since the arrival of humans ca 1000 years ago, due to both loss of habitat and hunting. A simple biogeographical hypothesis suggests that the southern South Island population is a remnant of the original population. This then colonised northward and diverged⁷.

The kiwis are an ancient lineage, judging from Gondwanaland distributions, and have had 40–80 million years to evolve in the isolation of New Zealand. Baker *et al.* used the RFLP (restriction fragment length polymorphism) clock of 2% sequence divergence per 1 million years to estimate divergence in New Zealand. They estimate that the basal population diverged from the Okarito population 900,000 years ago. The divergence between the Okarito and North Island populations would have occurred 500,000 years ago and that within the North Island populations, 200,000 years ago.

To summarize, the truly remarkable finding of this work is the fact that each population has private alleles for cytochrome b. The value of their work lies in their re-classification of the brown kiwi, which sheds new light on its status and makes it necessary to reevaluate conservation priorities. This work emphasizes the role of molecular genetics in conservation biology and stresses the need to continuously assess and review conservation practices. Certainly various other factors such as population ecology, behaviour and even aesthetic value may need to be taken into consideration, but this should in no way detract from the role that molecular genetics has in the conservation biology of tomorrow.

Patenting and commercializing biotechnology inventions

Suresh Chandran

To someone with a viable invention and no production resources or finance, a patent can give options otherwise not possible. Patents attract capital, help source research funds and provide licensing opportunities. Yet patenting is an expensive business. Even though, filing a complete specification in India may cost only Rs 200, the attorneys' fee may amount to hundred times that figure! Since most therapeutic, diagnostic or food product inventions have no prospect of grant in India and since the market prospects are often better in another country, it makes commercial sense to secure patents in foreign countries. Even once a patent is granted, costs continue. Maintenance, renewals, defence and active exploitation of the rights, monitoring competitor activity, etc. will follow. The costs of pursuing patent protection must therefore be balanced against the holding of granted patents or pending patent applications.

Some pointers can prove helpful. One can begin by asking: Is the invention really *new*? Is it commercially attractive? Is there a market need for the invention or must it be developed? Is the invention a marked improvement over currently available solutions? Is the merit easily demonstrable? A great majority of patents are commercial flops. If the commercial value of the invention is low, patenting efforts should be abandoned. Also if the invention is in a 'hot' area, the likelihood of the technology advancing before the invention is granted a patent is very real. The cost may not justify patenting if protection is short-term. Another vital decision is at what point in time should the inventor initiate filing procedures without compromising the validity or the scope of the ensuing patent at a later date? Mostly these are business decisions and can benefit from the informed opinion of patent attorneys. There is also the folly of rushing too early to file a patent. Technology takes time to mature for markets. If one is not careful, by the time the technology is ready for commercial exploitation, its patent-life would have run out. This is more so for biotechnology,

where regulatory approval takes several years of the patent life.

Of the various intellectual properties, utility patents and trade secrets are the most important in biotechnology. Several kinds of biotechnology-related products can be patented. These include: transformed cells, isolated proteins, mutant proteins and active-site portions of antibodies (*Cellular and molecular biology*); transgenic plants and animals (*Genetic engineering*); methods for preparing MoAbs, MoAbs with various specificities against various microbial antigens, hormones, endotoxins, etc. (*Hybridomas*); EIAs, labelled antibodies for scanning (*Diagnostics*); recombinant vaccines, antibiotics, therapeutic peptides, hormones etc. (*Biologicals, therapeutics*). Use claims can be handy when the processes are well known, and only say the microbe varies. All these inventions besides being eligible subject matter of patents, should comply with the conditions of novelty, utility, non-obviousness and enablement.

Using patents and trade-secrets simultaneously

While the trade-secret protects the invention by withholding information, the patent protects by disclosing information. Indeed, a trade-secret is an ideal form of protection as it does not cost anything and lasts forever, at least until it is discovered by reverse engineering. Trade secrets can be licensed out but prior to doing so, it is critical to enter into a confidentiality agreement with the potential licensee. Employees who must have access to such trade secret information must have express confidentiality obligations and be schooled against inadvertent disclosure.

Biological material can be replicated in large quantities from minute amounts of the starting material, be it clones, cell lines, gene sequences, etc. Loss of proprietary control over the material can mean serious consequences to the owner of the material and therefore it is increasingly important to institute agreements by resident as well as visiting

scientists on the use of proprietary biological material. Cases of lost clones and cell-lines from publicly funded laboratories finding their way into private hands are not unheard of.

The hybridoma for the generation of specific monoclonal antibody against a specific antigen is often kept as know-how. The microbial strain disclosed in a patent and commercially exploited need not be the same, as improved strains are employed in fermentation. Media composition, culture conditions, isolation and purification processes for products can be maintained as know-how. Clinical data or toxicology data may also be withheld as know-how. Even when a patent application is to be filed, there may be ancillary technologies that need not figure in the application but are important to make the product that embodies the patented invention. These are better preserved as trade secrets than as patents. It may be possible to practise both patents and trade-secrets together and it is advisable to disclose only the minimal information mandated by the law for grant of a patent.

Licensing mechanisms

Where funds are scarce as in universities and most publicly funded research institutes, the decision to file a patent is itself risky. The obvious strategy then is to find a licensee who will bear or at least share patenting cost. Intellectual property administration and technology licensing are discreet but inter-related activities. New patterns of technology licensing relationships are emerging and these range from ordinary licenses, marketing partnerships to joint ventures. Research institutions that are publicly funded generally have primary commitment to public good followed by creation of knowledge. Pursuing these goals and simultaneously making some money off the research requires adequate policy decisions at the administrative level because technology transfer activities do affect the freedom of the faculty to the choice of the research project, the right to publish where and

COMMENTARY

when and also to the choice of collaborators. With biotechnology inventions in general, commercialization is capital-intensive. It is advisable for small research institutions to make a deal of some sort with a larger company which has the requisite resources for successful commercialization.

Licensing

Exclusive, semi-exclusive or non-exclusive licence may be opted. Licences may also be granted on the basis of territory or field of application. The stage of development of the technology, market size and the level of protection available influence licensing activity. The strength of the patent is a major factor in licensing negotiations. However, it is unwise to put away negotiations till grant of a patent as this would mean throwing away precious time for product-development and blunt a major competitive advantage. Market research, technology evaluation and patent search should precede technology transfer and licensing. The act of selecting the *right* licensee who is capable of developing and commercializing the invention needs to be repeatedly emphasized. Some traits one should be looking for in licensees include: (i) the capability for absorption of the invention and its adaptation to field use, (ii) financial strengths in case regulatory approval and development for the product is envisaged, and (iii) the motivation of the company to commercialize the invention. Often technologies are bought by companies to stifle competition to their own products. It is therefore desirable that one looks up the company's product line and ensure that there is no clash of interest. Some of this information can be obtained from the annual reports of the potential licensees, their business plans, the range of products they intend to bring out and the markets they compete in, etc. These can help compare potential candidates for negotiating a licence. It is almost improbable to find the 'ideal' licensee and compromises have to be made. The

diverse objectives of the partners makes for a conflict of interest situation. Contentious issues often pertain to the:

Scopes of the licence; Value of the technology—quantum and timing of payments; Determination of milestones, terms of intervention; Indemnity and insurance, e.g. where biologicals for human use are involved.

A win-win attitude from the beginning of the partnership is essential. It should be realized that only when the invention is successfully commercialized, royalties would accrue. Industries must also on their part appreciate the limitations of research institutes and not view licensing negotiations as a one-time opportunity to seize advantage. Two related issues from experience, which in retrospect are very critical to successful technology transfer are, the incorporation in the licence document of a fool-proof reporting system to document the licensee's efforts at commercialization. This would aid the licensor initiate intervention procedures if progress is wanting. The second issue concerns ensuring meticulous royalty/sales record keeping. This will facilitate access of the licensor to audited royalty payment records. It must also be settled as to who in the partnership would bear the costs of infringement litigations if any, the company, the institute or jointly. Retaining know-how helps salvage the invention in case somebody succeeds in working around the patent. Technology-pricing is also tricky. If the technology will have a short life, it is a correct strategy to negotiate for substantial lumpsum payments in the first years. Companies on the other hand emphasize on milestone payments for any 'unproven' technology they may have taken up from the research institute. A reasonable compromise approach should be to spread the licence fee in instalments dictated by the various milestones achieved in the technology transfer process. The licensee not pursuing development of the invention towards its commercialization, has often been the cause of worry of many research insti-

tutes, including mine. If progress is not good enough, the institute should be in a position to call off the deal and find a new licensee early enough. Such intervention clauses have to be incorporated into the agreement. If the institute insists on annual licence maintenance fee, and if this quantum is increased over subsequent years, companies may be prompted to bring technologies from the back-burner and actively pursue development. Else if their interest has waned, they would request for termination of the agreement. Either way, for the institute it is better than the unpredictable wait. Successful licensing negotiations appreciate that every eventuality cannot be covered.

In the coming years technology licensing will be even more demanding. In order to be competitive, techno-enterprises may require major readjustments that call for operational flexibility and a fast response time—a trait normally not endowed to public funded research organizations. It is highly unlikely for scientists going about their usual chores to fully comprehend the implications of the law or business strategy. Their talents are best exploited in their own disciplines. The need for the hour is to nurture a band of technology transfer specialists, scientific 'dilettantes' if you may, with a hard nose for business. They should be able to sense research developments in their respective institutes that have potential for industrial applications and then successfully interface with the industry that requires this development. Most Western universities and research institutions have incorporated a technology licensing office within their organizational setup. Perhaps it is time we began to appreciate this fact and modify our approaches to suit the changing scenario.

A non-radioactive method for detection of Tn5 Kanamycin phosphotransferase activity in cyanobacteria

The wide use of Kanamycin phosphotransferase encoding gene, also known as NPT II gene, as one of the reporter genes in transformation studies has prompted the development of a number of procedures to detect and assay Kanamycin phosphotransferase in the transformed cells¹⁻³. All procedures reported so far need the use of radioactive ATP and also adequate care to account for other phosphotransferase activities in crude cell extracts. The present report deals with a simple, non-radioactive assay for Kanamycin phosphotransferase in two genetically transformed cyanobacteria.

The cyanobacteria, *Oscillatoria* sp. MKU277 and *Westiellopsis* sp. MKU154 isolated from rice field soils were electro-transformed using pRL1063a. The plasmid contained psbA promoter from *Amaranthus hybridus* and downstream to that were five genes namely, Neomycin/Kanamycin phosphotransferase gene (Tn5), Bleomycin resistance gene, Streptomycin resistance gene and *luxA* and *luxB* of *Vibrio fischeri*. Transformants growing in BG-11 medium containing 50 µg/ml of Kanamycin were harvested at the exponential stage, washed several times with Tris (100 mM pH 8.0) containing 10 mM MgCl₂ and suspended in the same buffer. PMSF was added to a final concentration of 5 mM. Cell suspension was sonicated and the lysate was clarified by centrifuging at 10,000 g for 10 min at 4°C. The clear lysate was transferred to a fresh sterile Eppendorf tube and stored at 0°C until use. Protein content in the lysate was estimated following Bradford's procedure⁴.

Reaction mixture contained 50 µg to 100 µg crude protein, 1.0 mM ATP and 4 µg Kanamycin. Reaction was carried out at 16°C for 12 h. *E. coli* HB101 from

exponential growth phase was mixed with LB soft agar (0.7%) and spread on plates. Soon after agar solidification, sterile Whatman No. 1 filter paper discs were carefully placed on the agar surface. Equal volume of samples from various treatments were spotted on the discs. Kanamycin

with ATP alone was used as control. The plates were incubated at 37°C for 24 h and the inhibition zones were qualitatively assayed.

When the sizes of inhibition zone formed around the discs (Figure 1 a, b) were compared, there was a significant reduction in the inhibition zone around the discs containing Kanamycin treated with lysate prepared from transformed cyanobacteria, indicating inactivation of Kanamycin due to phosphorylation. Inactivation of Kanamycin depended on the amount of protein added and the time of incubation. 50 µg crude protein was required to inactivate 4 µg of Kanamycin.

Figure 1 a, b. *E. coli* sensitivity to phosphorylated and non-phosphorylated Kanamycin. a, *Westiellopsis* sp. MKU154; b, *Oscillatoria* sp. MKU277. C – disc with untreated Kanamycin (control), W – disc with Kanamycin treated with wild type cell lysate; and T – disc with Kanamycin treated with lysates of transformed cells. pRL1063a was used for transforming the cyanobacterial strains.

DNA sequence analysis has emerged as one of the major disciplines of theoretical biology and has become an essential tool for study in molecular biology. In this article we review various methods currently available for the analysis of genomes and large-scale DNA sequences in order to detect potential genes out of sequence information.

THE extreme diversity that exists among biological systems is essentially governed by the information content of DNA molecules that make up the hereditary elements – collectively called the genome – which are transferred from one individual to another¹. Genetic information is decoded through the ‘genetic code’, which allows specific proteins to be synthesized according to the information present in DNA.

Many features of this genetic code are by now quite well-known². DNA molecules are composed of four nucleotides, the purines adenine (A) and guanine (G) and the pyrimidines, thymine (T) and cytosine (C). The three-dimensional structure of DNA is double helical, with nucleotides on the two strands paired A–T and G–C. The actual arrangement, i.e. the sequence, and the length of the DNA differs from organism to organism and determines its complete biology. One major function of the DNA is to manufacture specific proteins, and nucleotide sequences that contain this information are called the protein-coding regions or genes. There are also ancillary regions of the DNA which regulate and control expression of the proteins at specific times and under specific conditions.

At the same time, there are vast stretches of DNA sequence, principally in higher organisms, whose function is not yet known¹. Thus, it is still not possible to predict the complete biological functions of a given organism in spite of knowing the complete sequence of its genome. Gene functions can be experimentally determined using the techniques of molecular genetics and biochemistry. Given the time taken for these experiments, though, analysis of a complete genome is still an intractable task. Moreover, for most organisms, such experimental methods and approaches are not yet feasible. Thus, the development of theoretical and computational methods^{3,4} for analysis of DNA sequences could significantly aid and accelerate understanding of functions of different regions of DNA.

Availability of entire genome sequences of organisms can help, at the very least, to establish a complete genetic map of the organisms. Further, a comparative analysis of the genomes of a given family of organisms can help determine the minimal set of genes necessary for development and organization within that family. However, the large amounts of sequence information already available and continuously pouring in (in sequence libraries or repositories such as GenBank) pose a challenge, insofar as interpretation and analysis is concerned. There are several ongoing projects to sequence the entire genome of a number of organisms. Within the next few years the intention is to have a complete genome map of organisms such as *Drosophila melanogaster* (genome length \approx 165 Mbp, consisting of \approx 15000 genes), *Escherichia coli* (4.7 Mbp, 3000 genes), *Arabidopsis thaliana* (100 Mbp, 13100 genes), nematode *Caenorhabditis elegans* (100 Mbp, 15000 genes), the puffer-fish *Fugu rubripes* (390 Mbp, 80000 genes) and the human genome (3000 Mbp, 100000 genes). Recently, the entire genomes of *Haemophilus influenzae* (1.83 Mbp, 1727 genes) and *Mycoplasma genitalium* (0.58 Mbp, 482 genes) have been sequenced^{5,6}, and the entire genome sequence of yeast *Saccharomyces cerevisiae* (12.5 Mbp, 6400 genes) is expected in a few months.

Megabasepair DNA sequencing is, by now, a well-developed technology⁵. In the standard strategy, the genome is organized into a library of overlapping fragments, randomly cloned into a number of available vectors such as cosmids, phage P1, BAC or YAC. These vectors are designed to accept large fragments of DNA so that the entire genome of an organism is represented in the library. The choice of a specific cloning vector, to a large extent, depends upon the size of a specific genome. The large fragments are further subcloned in usually M13-based plasmid vectors, to get short stretches of DNA, which are sequenced using Sanger’s dideoxy chain termination method⁷. These segments are then re-assembled to form the genome with the help of overlaps, filling of gaps, etc. To accomplish the task of assembling the sequence of a large genome in a reasonable time-span, there is need for the continual development of innovative methods, especially those leading to automation⁸, which can further accelerate the speed of sequencing. Currently, a ‘random shotgun’ method^{5,6} has been used for *H. influenzae* and *M.*

genitulum sequences where the genome was randomly cut into segments and sequenced, with alignment done entirely on computer. This approach is feasible only with short genomes or cloned DNA fragments.

The central issue, stated simply, is to identify the *functional* regions of the sequences – the genes on the genome. As mentioned before, in a complex genome, only a small part is functional, in that it is decoded into a protein with the amino acid sequence determined by the DNA sequence. Another small part performs regulatory role by determining the time and extent of decoding in the life of an organism. Protein-coding DNA, along with associated regulatory sequences, is what 'makes sense'. However, a major part of the genome is composed of highly repetitive sequences of unknown or uncertain function – which were previously termed 'junk' or 'selfish' DNA. Thus the identification of protein-coding regions on the genome becomes a major goal of DNA sequencing and sequence analysis.

DNA can be considered as a linear string of the symbols, A, T, G, and C, and it is necessary to specify the sequence along either one of the strands alone since the sequence along the complementary strand is automatically specified. Proteins are synthesized by reading a code from DNA sequence, with a triplet of nucleotides – a codon – corresponding to a given amino acid. Since 20 amino acids are the constituents of naturally occurring proteins, and there are $64 (=4^3)$ codons, the genetic code is degenerate. The elementary grammar of the genetic code also includes a rule for initiation of protein synthesis (the start codon) and a rule to signal the end (the three stop or non-sense codons) (Figure 1).

The task of gene recognition and identification poses a challenge for several reasons. One can imagine identifying genes by one of two possible routes, either from the expressed protein back to the DNA or from the DNA directly. The route from the protein back to the DNA is made difficult (and uncertain) by the fact that

the amino acid-to-codon correspondence is not unique. Since a complete knowledge of the sequences of all proteins in an organism is a distant goal, this approach is of limited utility. In any case, identifying a gene is not simply a matter of finding an open reading frame (ORF), namely a portion of DNA of length at least 100 bp which starts with a start codon and ends with a stop codon (with no other intermediate stop codons). While prokaryotic genes are often continuous ORFs, the expressed part of a gene in the majority of eukaryotes is split into several discrete segments called 'exons' which are interspersed with noncoding intermediate regions, the 'introns'. Exons may be mixed and matched in various combinations to create new genes, and sometimes one gene's exon may be another gene's intron¹. The entire gene is transcribed into an RNA molecule, from which introns are spliced out, resulting in a messenger RNA that is a continuous ORF and is translated into the corresponding polypeptide.

There are several theoretical approaches to the problem of identifying coding regions in DNA sequences. A variety of mathematical techniques have been brought into play; these include statistical analysis, stochastic modelling, dynamical systems theory and dynamical programming. Current developments in the physical sciences such as chaos theory or the study of neural networks have also been applied, with equal effectiveness. Most of these methods rely quite heavily on computational tools, and the past decade has seen the development of several computer programs that accomplish the task of predicting the coding properties of unknown sequences with varying degrees of success.

The purpose of this article is to present an exposition of the current state of the art of gene identification through computational (*in silico*) methods. In the following section, we discuss the desirable features of coding sequence finders in general, and in this context describe several of the currently employed techniques for gene identification. These methods include both prokaryotic gene detection methods which need to look for coding ORFs, as well as eukaryotic gene detectors, that must locate exons and also determine how these are to be joined in order to make a functional gene. While we have tried to describe the main methods currently employed, our list is not exhaustive; other techniques and algorithms have been reviewed recently by Fickett⁹ and Burset and Guigó¹⁰. This is followed by a discussion and summary.

Gene identification

Given a genome sequence, the task is to locate all the genes. In an ideal situation, this implies identifying all the exonic, intronic and intergenic regions, and start and stop codons pertaining to each gene.

Figure 1. Schematic of the different regions in and around a gene in a genomic sequence, showing the organization of exons, introns, initiation and termination sites, intergenic spacers and promoters.

Gene-finding methods can be classified¹¹ as being *signal-based*, *content-based*, or, as is increasingly more efficient, a combination of both. Given a DNA sequence, there are six reading frames to be examined. These arise from the three possibilities for the origin of the sequence (owing to the triplet nature of the codon) and the two possibilities for the relevant strand of DNA. Signal-based techniques look for a signature in the sequences – start and stop codons, promoters, consensus splice sites, elements upstream of a gene which determine the transcription start site, polyadenylation signal at the 3'-end of the messenger RNA transcripts and similar motifs. Content methods look for codon usage biases, oligonucleotide frequencies, correlation exponents or related similar indicators.

Three measures which are used to evaluate the performance of a gene-finding technique are the sensitivity S_n , the specificity S_p , and the correlation coefficient C_c . These are defined as¹²

$$S_n = \frac{TP}{TP + FN},$$

$$S_p = \frac{TP}{TP + FP},$$

$$C_c = \frac{TP \cdot TN - FP \cdot FN}{\sqrt{(TP + FP)(FP + TN)(TP + FN)(TN + FN)}}, \quad (1)$$

where FP is the number of false positives, i.e. the number of bases *predicted* as coding, but which are subsequently, through experiments or homology, declared noncoding. Similarly, FN , the number of false negatives, is defined as the number of bases, which are experimentally confirmed as coding but are declared noncoding by the computational method. TP are the true positives, i.e. the number of bases correctly predicted as exonic, while TN are the true negatives, the bases correctly predicted as noncoding. The average of the specificity and sensitivity¹² gives some measure of the accuracy of a given method. Although the above measures are evaluated at the nucleotide level, these can similarly be defined at the exon level¹⁰.

Looking for a signal alone has its drawbacks, chief among which are the degeneracy and the lack of unequivocal definitions of signals, which can reduce the sensitivity or specificity. Looking for content alone involves the calculation of several statistical measures, the analysis of which is organism-specific, and which does not always give unambiguous results for the coding potential of a sequence.

The smallest eukaryotic genes are typically about 300 bp in length. Therefore, the existence of an open reading frame (ORF) of reasonable length suggests the *possibility* of a gene, but this alone is insufficient as

evidence of coding potential, since start and stop codons could occur randomly with some (small) probability. In addition, single base errors in sequencing cause *frame-shifts*, which may abruptly and erroneously terminate an otherwise long ORF.

'Compositional heterogeneity' is a hallmark of functional proteins. Examination of the entire protein databank (PIR database) shows that the 20 different amino acids are used in very different proportions in functional proteins (Table 1). This automatically implies that there must, similarly, be fairly stringent constraints on nucleotide usage at the level of the DNA sequence. All genomes have a bias in the base composition, possibly decided by evolution. This restricts the choice of which codons are used in designating a given amino acid. Thus coding regions have a very *unequal* usage of codons.

Constraints on the amino acid composition of functional proteins thus can lead to regularities in a coding sequence. This feature can be probed with the help of certain statistical measures, which have been used in the earliest methods to locate genes. These are discussed in the following subsection.

Oligonucleotide distribution-based methods

In these methods, 'unequal codon usage' is the fundamental measure for identifying protein coding stretches. This asymmetry in codon frequency gives rise to compositional variations. However, it has been observed that unequal usage of amino acids, without the codon preference or base composition bias, is enough to produce significant compositional variations in all the three reading frames for codons and bases. It is useful to go

Table 1. Average amino acid usage by proteins

Amino acid	Frequency (%)
Ala	7.60
Arg	5.23
Asn	4.36
Asp	5.21
Cys	1.89
Gln	4.17
Glu	6.32
Gly	7.19
His	2.28
Ile	5.29
Leu	5.81
Lys	9.17
Met	2.29
Phe	3.97
Pro	5.20
Ser	7.15
Thr	5.87
Trp	1.31
Tyr	3.21
Val	6.49

beyond the level of the trinucleotide codon and examine the distribution of other oligomers, which is also quite distinctive.

Testcode. This observation can be used to develop a method to distinguish coding regions from non-coding ones in genomes^{14,15}. The first step involves setting up a codon frequency table for coding regions, which can be achieved by using prior information coming from previously determined genes or open reading frames. Then a window is moved along the sequence, three bases at a time. For each window, the codon frequency is evaluated in each of the three reading frames, and compared to the one evaluated for a known set of genes. The frame in which the deviation is comparable to that for the test set of genes is adjudged as a coding frame, whereas if the deviation is large in all the three frames the region is identified as noncoding.

While asymmetry in codon usage has been used by Staden¹⁵ to develop a method for the identification of genes, Fickett¹⁴ exploited compositional variations observed in coding and noncoding regions. In the technique TESTCODE a total of eight parameters—four positional and four content parameters, one for each nucleotide—are used to judge whether a sequence is coding or not. The positional parameter is the ratio

$$P_{\alpha} = \text{MAX}(f_1^{\alpha}, f_2^{\alpha}, f_3^{\alpha}) / \text{MIN}(f_1^{\alpha}, f_2^{\alpha}, f_3^{\alpha}), \quad (2)$$

where f_i^{α} is the frequency of the base α at position i in the codon, and measures the extent to which a base is favoured in one codon position over another. Since it is not relevant which of the codon position favours the base, the positional parameters have fairly similar distributions in all sequences, regardless of the differences in codon usage strategy between organisms. The content parameter for a nucleotide is simply its frequency.

A standardized table, giving the coding probability of a sequence for a range of each of the eight parameters can be devised from existing sequence information available. (In Fickett's implementation of TESTCODE, this table derives from the Los Alamos Sequence Library.) Each of these parameters is used with a different weight, determined as follows: The parameter is used alone to predict coding function, from the standardized table, and the sequence deemed to be coding if the probability exceeds 1/2. The weight of the parameter is the percentage of times this guess is correct, less 50% (the random level). For a test sequence of unknown functionality, one calculates the eight parameters and obtains the probabilities p_i and weights w_i for each of them from the tables. The sum $\sum_{i=1}^8 p_i w_i$ is evaluated to get the TESTCODE indicator, and the prediction is then obtained from the standardized look-up table of the sample set.

By itself TESTCODE cannot find exact boundaries for coding sequences, but it is well adapted for combination with other techniques such as searches for ORFs, ribosome binding sites, intron boundaries. The reliability of the method when checked by taking half of the sequences in the Los Alamos Library as sample set and the other half as test set gives an error rate of prediction of around 5%.

GeneMark. Differences in oligonucleotide frequencies have been exploited in the technique GeneMark¹⁶. The Markov model is a convenient means for evaluating the probabilities of occurrence of oligonucleotides while taking into account correlations between frequencies in different positions. This model has been widely used for the study of one-dimensional strings generated in dynamical systems or those involved in language theories, to assess the correlation structure of the sequences and frequencies of words of length m in strings of length N .

A Markov process assumes that the state of a system at time t depends on its state at time $t-1$ only. This rule, when interpreted for strings of symbols, states that the probability of the symbol α_i at position i depends only on the probability of the symbol α_{i-1} at position $i-1$. For DNA sequences, this model reproduces the dinucleotide frequencies. For higher oligonucleotide frequencies, higher order Markov processes have to be invoked. For example, in a second order Markov model, the probability of symbol α_i at position i depends on the probability of the doublet $\alpha_{i-1}\alpha_{i-2}$ at positions $i-1$ and $i-2$, and this reproduces the trinucleotide frequencies in DNA.

Since correlation between nucleotides differs in coding and noncoding sequences, the corresponding Markov models are also different. The fact that the reading frame plays an important role in coding regions is accounted for by considering 'phased' or non-homogeneous Markov models. In these the probability of an oligonucleotide depends on which of the three codon positions its first nucleotide occupies. Recent studies have shown that in-phase hexamer statistics are very effective in distinguishing coding regions, since they take into account not only the codon bias but also the correlations between the various positions of neighbouring codons. Thus GeneMark uses phased fifth order Markov chains to make its predictions of coding regions.

A sliding window is used, which moves along the sequence in steps, which are a multiple of three. For each window, the algorithm calculates if the DNA fragment is modelled by the phased Markov model in one of the six frames or the ordinary Markov model. In the first-order Markov model (which can be generalized to fifth order, below), the probability that a

sequence S of length L is noncoding is given by the ordinary Markov chain formula

$$P(S|NON) = P_N^0(\alpha_1) \times P_N(\alpha_2|\alpha_1) \times \dots \times P_N(\alpha_L|\alpha_{L-1}). \quad (3)$$

Here, $P_N(\alpha_L|\alpha_{L-1})$ is the conditional probability of observing the nucleotide α_L in position L , given that α_{L-1} is observed at position $L-1$, and P_N^0 is the initial probability. P_N values are calculated on the training set of noncoding sequences.

The probability of the frame 1 in S being coding is given by the phased Markov chain

$$P(S|COD_1) = P_1^0(\alpha_1) \times P_1(\alpha_2|\alpha_1) \times P_2(\alpha_3|\alpha_2) \times P_3(\alpha_4|\alpha_3) \times P_1(\alpha_5|\alpha_4) \times \dots \times P_2(\alpha_L|\alpha_{L-1}). \quad (4)$$

Here, P_1 , P_2 and P_3 are respectively the probabilities determined for the three codon positions in frame 1 and P_1^0 is the initial probability. The values P_i and P_i^0 are defined from the training set of coding sequences. For the other frames (2–6) the probabilities $P(S|COD_m)$ are defined by similar formulae. The fifth order case is a generalization of the first order model and the probabilities are determined from Bayes formula¹⁷.

$$P(COD_m|S) = P(S|COD_m) \times P(COD_m) \sum_{m=1}^6 P(S|COD_m) \times P(COD_m) + P(S|NON) \times P(NON), \quad (5)$$

where $P(COD_m|S)$ is the *a priori* probability that an unspecified fragment S is coding and its first nucleotide is located in the codon position defined by index m . $P(NON)$ is the probability that S is noncoding and is assumed to be the same as $P(COD_m)$ and equal to 1/2.

For each sequence to be analysed GeneMark determines all possible ORFs and the average value of $P(COD_m|S)$ is computed for each ORF. If the value is greater than 0.5, the cutoff, the ORF is included in the list of predicted genes. If there is more than one reading frame in which this probability is greater than 0.5, the frame with a higher probability is chosen. When applied to the unannotated sequences of *E. coli*, the technique found many new genes¹⁷.

GeneId. The simple method described above can be made more sophisticated. For example, GeneId¹⁸, a hierarchical rule-based system for identifying probable protein coding genes, starts by identifying all possible signals, such as initiation and stop codons, donor and acceptor sites, promoters, poly-adenylation signals and assigns each a rank, according to the preferred ordering

and spacing among the various sites. Using these 'atomic sites', all possible exons are constructed and ranked by computing some of the statistically significant properties equivalent to those described above and comparing with a cutoff value obtained from a sample set. Thus each exon is sequentially filtered through the cutoff for each of the statistical measures. These exons are then classified into equivalence classes. Two exons are said to be equivalent if they occur in exactly the same gene. These classes of equivalent exons are then assembled to form the gene. A function of values assigned to each of the component exon classes is assigned to the potential gene, and this score is used to rank the gene¹⁸.

The sample sets that have been used in GeneId consist of the first, internal and terminal exons from the primate, mammalian, rodent and vertebrate groups of GenBank 64.0, excluding those with alternative splicing sites, mutants, pseudogenes, etc. These have been used to derive profiles for the prediction of the various gene-finding signals and to calculate the cut-off values for the variables used to derive the rules through which the exons are filtered. Weights are assigned to the sample set of exons to correct for the unequal representation of homologous gene families in the database. (Each family of similar exons is assigned a weight of 1.0, the weights of the sequences are assigned according to the topology of the family, and these weights are used in the derivation of the profiles.)

Given a DNA sequence, the first step involves the identification of the various atomic sites. These are confirmed by several context-based rules. For example, the first ATG does not necessarily correspond to the first AUG of the mRNA. To determine the potential start site, sequence context and distance to the cap site are used as criteria. The profile for initiation codon is derived using first expressed exons.

Similar weighted profiles are constructed for donor and acceptor sites from a set of internal exons, and respective cut-offs are established. In the case of start codons, the distance of the codon to the cap site is computed, and from the frequency distribution of this distance, a cut-off can be determined beyond which very few exons have their start. Similarly, for the stop codon, the distance to the end of transcription unit is computed for the set of last exons, and from the frequency distribution, the critical distance can be fixed. These statistics are used to establish the authenticity of a given exon.

Apart from these, some of the standard statistical measures – nucleotide frequency, positional correlations – can also be used to further filter the exons. The average correlation coefficient and sensitivity for this method, for 222 sequences from a variety of organisms – human, chicken, goat, rat, etc. – are 0.79 and 0.88, respectively.

Neural networks

Neural networks¹⁹ are numerical algorithms which allow a system to learn, recognize and classify patterns. The underlying idea for these methods derives from the nervous system of living organisms. A model neuron is a simplified version of the biological neuron, and is a two-state threshold device having outputs +1 or 0 corresponding to the firing or non-firing state of the neuron, respectively. A multiply-connected collection of model neurons forms a neural network¹⁹.

The simplest application of the collective computation of a neural network is associative memory, i.e. storage and recall of information by association with other information. This process is modelled by a neural network as follows. For a set of N two-state neurons the total number of patterns are 2^N and P of these patterns are stored in memory. If a new (or 'test') pattern is now presented to the network, it should be able to recall the stored pattern that resembles it most strongly. This is achieved by defining a dissipative dynamics on a surface wherein the stored patterns are made to correspond to local minima, and the test pattern is allowed to evolve under the dynamics so as to flow into the local minimum with the closest pattern match. The dynamical evolution of the state s_i of neuron i in the presented pattern is defined as

$$s_i(t+1) = \text{Sgn} \left(\sum_{j=1}^N w_{ij} s_j(t) - \theta_i \right), \quad (6)$$

where s_i is the state of neuron i , w_{ij} are the synaptic coupling strengths and the threshold θ_i is usually chosen to be 0, for simplicity. The choice of the weights, or coupling strengths, defines the learning rule of the network. The earliest of learning rules used is the Hebb rule, which defines the coupling strength as

$$w_{ij} = \frac{1}{N} \sum_{\mu=1}^P \sigma_i^\mu \sigma_j^\mu, \quad (7)$$

where σ_i^μ is the state of neuron i , in the stored pattern μ .

Similar to the task described above, of storing and recalling information, neural nets can be designed to recognize and classify patterns. Such nets have a fundamentally different structure, consisting of an input layer, a black-box consisting of one or several hidden layers, and an output layer. The signals received by the net through the neurons of the input layer are processed in the hidden layers, and the result is sent to the output layer. Since information flows in one direction these nets are called feed-forward layered networks or, more

simply, perceptrons. Again, in this case too the output signal depends on the input signal and the coupling strengths of the synapses,

$$S_i = f \left(\sum_k w_{ik} \sigma_k \right), \quad (8)$$

where S_i is the state of the i th neuron of the output layer and σ_k that of the k th neuron in the input layer. As before, the choice of the weights defines the learning rule. The learning is said to be supervised, if the output is known for a sample set and the weights, initially chosen randomly, are monitored by the output error. This learning is not very realistic, since it requires complete and detailed knowledge of the output, which is very uncharacteristic of the actual system they simulate. For this reason other concepts of learning have been studied, which are based on reward and penalty, for example. These come in the general class of unsupervised learning.

In supervised learning, an extensively used learning rule is the gradient learning. In this learning, the total deviation between the actual output and the desired output, and its gradient with respect to the synaptic weights, is computed. In the next iteration, the synapses are modified by a small fraction of the gradient. The disadvantage of this method is that it cannot be applied to perceptrons built with deterministic, binary-value neurons. The major advantage is that it can be generalized to multi-layered perceptrons. Multi-layered perceptrons become necessary because some very simple problems become intractable with simple perceptrons¹⁹.

A method based on the generalization of the gradient rule to multi-layered nets, is error back-propagation, when the gradient rule is applied recursively to the synapses of the output and those of the hidden layers. In applying the rule to the hidden layers, the gradient of the total output deviation with respect to the weights of the hidden layer is computed, and the weights are then modified by a small multiple of this gradient. Thus, the error at the output is propagated back to determine the weights of all the hidden layers. This is a very powerful learning rule, and has been used extensively.

GRAIL. The widely used method GRAIL employs a neural network algorithm to implement a method similar to that of GeneId. In this case, however, instead of looking for the various atomic sites, several statistical measures are evaluated and the multi-sensor neural network processes them to define a score for the coding region. As depicted in Figure 2, seven sensors are used, including Fickett's measure¹⁴, the positional base frequency to determine the coding frame, and hexamer frequencies. These are evaluated for a simple set, and

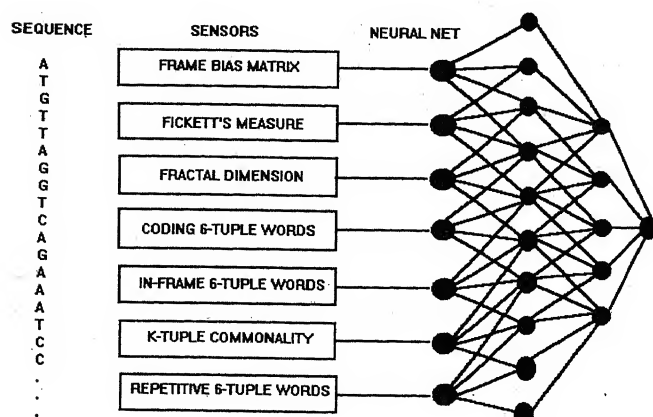

Figure 2. The neural network used by GRAIL with an input layer of seven nodes, two hidden layers of fourteen and 5 nodes respectively and an output layer of single node. (Adapted from ref. 20).

the weights of the measures are extracted. Using these weights the neural net evaluates potential coding regions.

The sample sequences originally used for the evaluation of the weights²⁰, were 18 genes from the human genome. A 99-base window, centered at each position, was used to evaluate seven sensors, scaled between 0.0 and 1.0. These values were passed through the neural net and at the end of the training, the weights of the net were extracted. The sensors used are:

1. *Frame bias matrix.* This is a 3×4 matrix containing the frequency with which a particular base occupies each of the three positions in a codon. This measure relies on the fact that while in the noncoding region or the incorrect reading frame of a coding region the distribution of positional frequencies is nearly uniform, in the coding frame there is a significant deviation from the random distribution. The standard bias matrix has been obtained from coding exons of human sequences. The correlation coefficient between the standard matrix and that of the three reading frames of each window is evaluated. The difference between the best and the worst coefficient is used as an indicator of the correct coding frame.
2. *Fickett's measures.* These are the same parameters used by Fickett in TESTCODE. The output of TESTCODE is used as the value of this sensor.
3. *Dinucleotide fractal dimension.* It is known that dinucleotide frequencies are far from random. The various dinucleotides can be grouped according to their frequencies of occurrence. It is thus possible to view a DNA sequence as a dynamic function, by examining transitions of sequential dinucleotides, i.e. asking whether the next dinucleotide belongs to the same frequency group or not. These fluctuations are characterized by a fractal dimension²¹. This dimension has a lower value in coding regions as compared to noncoding regions. Thus the

sensor value is the difference in the dimension between a reference value derived from introns and that for the test window.

4. *Coding 6-tuple word preferences.* This measure is the sum of the 6-tuple preferences, defined as the logarithmic ratio of the normalized frequency of 6-tuple words in coding and noncoding regions. It has been noticed²² that, in addition to uneven codon frequencies, there exist correlations between nucleotide positions of adjacent codons in coding exons. Hexamer, or dicodon, frequencies are a measure of both, the codon bias and correlations between nucleotides of neighbouring codons.

5. *Coding 6-tuple in-frame preferences.* This is the same as the previous measure, except that the 6-tuple frequencies are compared with the preference values of in-frame 6-tuples in coding DNA.

6. *Word commonality.* This is the logarithmic ratio of the normalized frequency to the expected random frequency of hexamers. The word commonality measure is summed over the entire window.

7. *Repetitive 6-tuple word preferences.* This measure is the same as the above, except that the comparison here is with several classes of repetitive DNA.

Sensor 1 helps to establish the correct reading frame of a coding sequence. Sensors 2–6 are various statistical measures, which are significantly different for coding and noncoding DNA. Sensor 7 is a negative indicator, since it is a statement that repetitive DNA rarely codes for protein.

These seven sensors form the nodes of the input layer to the neural network constructed in GRAIL. In addition, there are two hidden layers of 14 and 5 nodes, and an output node. For training sets, the correct output value (0 for noncoding and 1 for coding) is also provided. In the learning phase, the net compares the output value with its prediction and adjusts its weights, using the back-propagation algorithm. The net thus optimizes its performance by continuous evaluation of the output error.

When tested²⁰ on a sample set of human genes, the overall sensitivity and correlation coefficient was found to be 0.54 and 0.69 respectively. However, the performance of a later and improved version, GRAIL2 (ref. 23), on a similar data set, showed a significant improvement, with the overall correlation coefficients and sensitivity as 0.80 and 0.86 respectively.

GeneParser. GeneParser²⁴ combines the connectionist approach, adopted by GRAIL²⁰, with a recursive optimization procedure dynamic programming²⁵, to predict intron–exon structures of genes. The dynamic programming algorithm is used first to parse a sequence into basically four classes, namely introns, first, internal and last exons, subject to certain 'grammatical' constraints. In the second step, a neural network is trained to weigh

several content and site statistics, and score the intervals of interest in the sequence. Finally, the suboptimal solutions of the parsing problem are obtained and presented in a graphical format, enabling the user to identify which of the predicted splice junctions are most likely to be correct.

Like the previous technique, here also multiple lines of evidence are used to identify exons. The content statistics used in this case are in-frame hexamer frequencies, local compositional complexity, intron-exon length distributions, bulk hexamer frequencies and BLAST similarity scores²⁶. In the site statistics, splice sites and translation initiation sites were discriminated with the help of occurrence of specific nucleotides in the vicinity of the sites.

In-frame hexamers are used to determine the correct reading frame. The logarithmic ratio of the frequency of a hexamer to that of its frequency in a random sequence of the same base composition is summed over to define the hexamer score. Preferred hexamers have a positive score, while those avoided have a negative score. While in-frame hexamers are evaluated in a particular reading frame, bulk hexamer frequencies are calculated disregarding reading frames. These frequencies differ significantly between sequences of different functionality.

Local compositional complexity is quantified through the Shannon entropy²⁷ for oligonucleotides of length $L=8$, which provides a measure of redundancy. This quantity distinguishes between coding and noncoding regions by virtue of repetitive sequences which occur typically in noncoding regions. Error tolerance can be incorporated into the method by introducing random frameshift and substitution errors with predetermined error rates into the sequences of the training set.

The method was tested on 28 human sequences used by GeneId and GRAIL. The sensitivity and the correlation coefficient for this set turned out to be 0.87 and 0.78 for the latest version of GeneParser. This is a significant improvement as far as the sensitivity of the method is concerned.

Linguistic analysis

The spoken languages of the world have two remarkable features. The first is Zipf's law²⁸, which is essentially the observation that the frequency of word usage has a power-law dependence. A histogram of the total number of occurrences of each word in a text versus the rank of the word follows a power law, with an exponent $\xi \sim -1$. This is an empirical observation and is seen to hold for all languages²⁹.

The other common feature of all languages, is redundancy³⁰, i.e. words (or sentences) do not become unintelligible by the omission of some letters (or words).

This notion of redundancy can be quantified through the Shannon entropy. If $p^{(n)}(A_1, \dots, A_n)$ is the probability to find a word (A_1, \dots, A_n) in a string of length n then the Shannon entropy is defined as

$$H_n = -\sum p^{(n)}(A_1, \dots, A_n) \ln p^{(n)}(A_1, \dots, A_n). \quad (9)$$

Such analysis can also be adapted to DNA symbol sequences²⁹, if one can properly define the concept of a word. In coding regions, the 64 codons can be considered as words, but putative words in noncoding regions could have lengths greater than 3. The word of length n can be considered as a parameter that varies from three upward, and a DNA sequence is considered as an overlapping set of word n -tuples. Sequences from different categories of organisms were analysed²⁹, and the Zipf exponents were larger for noncoding sequences than for coding sequences – indeed the largest exponent obtained was for the noncoding sequences of *C. elegans*, $\xi=0.537$. This result (which is not entirely uncontroversial³¹) suggests out that noncoding regions were closer to the natural languages than the coding regions, and implies that noncoding regions may have a structured 'language'.

It is conceivable that this difference in language-like properties between coding and non-coding regions can be adapted to a method to distinguish between coding and noncoding regions, similar to the coding sequence finder (CSF) described in section 'Coding sequence finder' below. However, linguistic analysis-based methods for gene identification, on the other hand, exploit the formal structures of languages and grammars.

GenLang. Formal language theory views languages as sets of strings defined over some alphabet with concise sets of rules called grammars. Theoretically, for a given alphabet one can define an infinite number of languages. Grammars have been studied intensively with the help of computers, and have been used to describe the complex structures of strings of symbols. In the process computer programs, called parsers, have been developed, which are capable of determining whether a given string satisfies the rules of the grammar. These programs have been applied to the problem of searching for complex patterns specified by grammars, in a technique known as syntactic pattern recognition.

The information encoded in the DNA sequences uses an alphabet of four letters, with a set of rules determining the protein-coding regions. Thus the techniques of language theory can be applied to identify the syntactic patterns of the DNA language. The problem consists in defining the protein-encoding gene grammars. The core of the grammar¹² can be presented in the form of a binary tree (Figure 3). The root node is the gene, which is hierarchically built up. It is analogous to the sentence of a natural language. It consists of a start (and body)

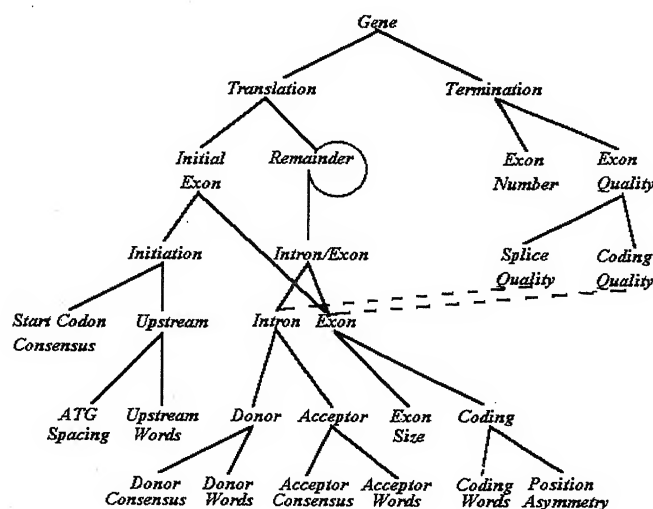

Figure 3. Graphical representation of the core grammar structure used in GenLang. (Adapted from ref. 12).

and a termination. There are various rules which define the start (first exon) and the body (internal exons and introns), and the termination (last exon). At the bottom of the tree are what are termed as 'leaf' rules, variously called sensors (neural network technique) or 'prelexical' in the linguistic context. These are derived directly from the sequence. There are 13 leaf rules used in GenLang, including rules for determining a true initiation of translation, such as consensus for the start codon, its distance from the ATG preceding it upstream, etc.

Each leaf rule is assigned a 'cost', or a threshold error, which it can accept. The cost of consensus sequence (signal), for example, is defined as the sum of the negative logarithm of individual base position frequencies, normalized so that the most likely base in each position contributes zero cost. Costs are propagated up the parse tree and summed at each node, which is connected to two leaves or other nodes, so that each subtree has its own threshold cost. The cost at node N is defined in terms of the costs of the two lower-level rules—left (L) and right (R) child—as follows

$$\text{Cost}_N = (1 - \mu) \text{Cost}_L + \mu \text{Cost}_R, \quad (10)$$

where μ is a mixing parameter, with values ranging between 0 and 1. As for the neural networks, values of μ are determined from sample sequences. In addition, each node is associated to a pair of threshold costs, θ_L and θ_R . If the cost accumulated from a subtree at a node exceeds the threshold cost, that path is discarded and the grammar may backtrack or retry the node at the next iteration. Even if a gene is developed successfully, the grammar can be made to backtrack, in an attempt to minimize the overall cost.

The training set currently used¹² consists of sequences from organisms including man, mouse, *Drosophila* and dicot plants clustered into groups of similar genes, as in GeneId, to take into account the over-representation of some classes of genes (e.g. globins) in the databank. The performance of the technique was assessed, using various measures, including the standard sensitivity and correlation coefficients. For a test set (also from the same organisms) these values were 0.83 and 0.77 respectively. The other measures were more stringent, such as the fraction of genes correctly predicted completely and the fraction of correctly predicted exons. Typical values for these were 0.1 and 0.5 respectively.

Correlation methods

One feature of all methods described above is that they are *context dependent*, i.e. in each case a sample set is required, and parameters obtained from this sample set are then used to determine the potential coding properties of a test sequence. Two approaches that do not require any particular prior information to determine the coding potential of a DNA sequence, which are based on the correlation properties, have recently been developed.

In recent years there has been a flurry of activity, primarily in the physics literature, on the study of long and short-ranged correlations in long genomic sequences. A widely used tool to study the short and long range correlation structure of symbolic strings is the discrete Fourier transform. For a symbolic sequence $\{S_j(\alpha)\}$, $j = 1, \dots, N$, of symbols $\{\alpha\}$ this can be defined as

$$S(f) = \sum_{\alpha} S_{\alpha}(f) = \sum_{\alpha} \frac{1}{N^2} \left| \sum_{j=1}^N S_{j\alpha} e^{2\pi i j f} \right|^2 \quad (11)$$

where

$$S_{j\alpha} = 1 \quad \text{if } S_j = \alpha \\ = 0 \quad \text{if } S_j \neq \alpha.$$

The analysis of a large set of coding and noncoding sequences has revealed^{32,33} that the Fourier transform of coding sequences has a distinct peak at frequency $f = 1/3$, as in Figure 4a, while this peak is absent from noncoding sequences as in Figure 4b, independent of organism and base composition. On the other hand, long-ranged correlations show up as a $1/f$ fall-off in the frequency, and this can be seen either in the simple power spectrum defined above^{34,35}, or in more involved analyses such as the wavelet transform³⁶.

Another method to detect long-range correlations proceeds through the construction of a so-called DNA walk³⁷, which is defined as follows. Starting from the origin of a square lattice, one considers a directed

Figure 4. The Fourier transform of a coding (a) and a noncoding (b) sequence from chromosome III of *S. cerevisiae*.

random walker who takes steps up or right according to the nature of the DNA sequence under analysis. For a pyrimidine at site i , the walker takes a step upward, $u(i) = +1$, and for a purine, a step rightward $u(i) = -1$. The net displacement $y(n)$ after n steps scales as $y(n) \sim n^\alpha$. For an uncorrelated or short-range correlated walk, the theory of random walks gives the well-known result that $\alpha = 0.5$, and thus deviations from this scaling behaviour are indicative of long-ranged correlations in the data.

One difficulty of applying this approach directly to DNA sequences is that, DNA has a patchy structure, i.e. the average base composition varies from region to region, and this can give rise to features similar to those observed in long-range correlations. To overcome

this difficulty, a technique termed Detrended Fluctuation Analysis (DFA)³⁸, which involves dividing the region of interest of length N , into N/l non-overlapping windows of length l is adopted. For each window, the ordinate of the least squares fit for the net displacement of the DNA walk is defined as the local trend, and the detrended walk is then defined as the difference between the original walk and the local trend. The variance about the local trend in each window is calculated and averaged over to give a quantity $F_d(l)$. It was shown that $F_d(l) \sim l^\alpha$, where $\alpha = 1/2$ for patchy, but otherwise uncorrelated or short-range correlated sequences, while for long-range correlations $\alpha > 1/2$.

Results of studies of several DNA sequences, separately analysed for coding and noncoding regions, have established the result that coding regions have short-range correlations, while noncoding and intronic regions have long-range correlations. Although this result is somewhat controversial³⁹, there is enough evidence to suggest that the scaling exponents do indeed behave differently in the two cases⁴⁰.

The above empirical observations can be adapted as the basis of techniques to then predict coding potential, either by looking for the presence of short-range correlations, in the Fourier method GeneScan³³ outlined below, or by looking for the absence of long-range correlations, as in the coding sequence finder (CSF) algorithm⁴¹.

Another technique developed⁴² to study the correlation structure of DNA sequence uses the ideas of the so-called chaos game. The chaos game representation (CGR) of a DNA sequence can be constructed as follows. The four corners of a square are labelled by the four nucleotides in DNA, A, T, G, C respectively. Starting from the origin (the centre of the square), a point is plotted midway to the corner corresponding to the first nucleotide of the sequence. Subsequent points are the successive midpoints between the previous point and the corner corresponding to the current nucleotide, as the sequence is read through. What emerges is a pictorial representation of the DNA sequence. The density of points in the different part of the square indicates the various correlations between nucleotides. For a random sequence, for example, the square fills up uniformly. This technique has so far been used only to classify⁴³ different groups of genes. The difficulty of using the technique to recognize coding regions is that a CGR pattern becomes distinct only for fairly long sequences (> 1000 bp).

GeneScan. In earlier work³³, we have used the existence of the $1/3$ periodicity in coding regions to develop the technique GeneScan which detects the coding potential in genomic regions as follows. A window of length M , is moved along a sequence of length N , and the *local* peak-to-noise ratio at $f = 1/3$, defined as

$P_M(j) = P(1/3)/\bar{P}$, is measured. Here $P(1/3)$ is the peak height at $f=1/3$, \bar{P} is the average peak height of the spectrum and j is the position of the centre of the window. Study of a very large number of previously identified genes and noncoding sequences has shown that the peak-to-noise ratio of the spectral feature at $f=1/3$ exceeds 4 in almost every coding sequence, while for a noncoding sequence, this ratio is less than 4 (and usually less than 3). This empirical observation can be used to set a threshold, which, if the local peak to noise, $P_M(j)$ exceeds, then the window is deemed to overlap with a coding region. This simple procedure thereby gives the approximate location of coding exons. Figure 5 shows a representative result, for bases 15000–25000 of *S. cerevisiae* chromosome III. The size of the window to be used depends on whether or not we expect short (<200 bp) exonic regions. Once the approximate position of the coding region is located, the sequences are further scanned to find, in any of the six reading frames, the exact location of the initiation and the stop codon, or the location of possible consensus splice sites. For prokaryotic genes, our procedure works extremely well, and a typical result, from the analysis of the *H. influenzae* genome is given in Table 2. We have similarly studied a host of organism ranging from *S. cerevisiae* (9 of the 16 chromosomes), *E. histolytica*, *A. vinelandii*, *A. californica*, *C. elegans*, *M. genitalium*

Figure 5. The results of window analysis using GeneScan on a stretch of the chromosome III of yeast. The regions where the graph exceeds the base (here taken as 4) indicate probable coding regions³³.

Table 2. Summary of results from GeneScan for the complete genome of *H. influenzae* (the quoted specificity and sensitivity are at the gene level)

ORFs reported ⁴⁵	1727
ORFs detected	1499
False positives	0
Specificity	1.0
Sensitivity	0.87
Genes reported ⁴⁶	933
Genes detected	867
Sensitivity	0.93

and several human genome sequences as well. The overall quality of the results is similar to that in Table 2.

For eukaryotic sequences, where exons can be very short, the scanning windows need to be adjusted to an optimal length. Furthermore, other techniques for locating splice sites to determine the exact location of the introns and exons also need to be used. As a consequence, the technique does not have the same level of sensitivity or specificity at the nucleotide level, for genes composed of several exonic regions³³, although the overall quality of results is very similar to that afforded by other techniques¹⁰.

Coding sequence finder. The observation of the difference in correlation exponents between coding and noncoding regions can also be implemented to scan a genome to determine the potential coding regions⁴¹. Here also, a window of length W is moved along the genomic sequence. For each window, a double logarithmic plot of $F_d(l)$ vs l is constructed. The exponent α is obtained as the (least squares) slope of this graph, and this value of α is plotted against the position of the window (defined as the centre of the window). For noncoding regions $\alpha > 0.5$, while for coding regions $\alpha \sim 0.5$. Thus a dip in the plot indicates a probable coding region and one can essentially read the coding regions off the graph; see Figure 6.

The major drawback of this method is the large size of the window required to observe long-range correlations, which sets a limit on the smallest size of coding region detectable (usually about 1000 bp). Furthermore, the boundaries of the coding stretches are only very

Figure 6. Typical results from the coding sequence-finder algorithm. A detrended DNA walk is constructed from a DNA sequence and the correlation exponent is determined for a stretch of about 1000 bp. The dip in the value of the scaling exponent indicates potential coding regions. (Adapted from ref. 41).

approximately determined by this method, although this can be improved by combining this with other techniques.

Discussion and summary

Rapid assessment of sequence information is possible only through computational techniques which are now being developed and refined. The different methods available have been briefly described and reviewed in the previous section, and it is clear that each algorithm or technique has something to offer.

Experience-based methods – for example those that use neural networks^{20,23,24} or prior information from Markov chain analysis^{16,18}, are currently the most widely used. These offer the advantages of pattern recognition and pattern selection. Methods that do not rely on prior information, such as those based on correlation properties^{33,41}, offer, in principle, the possibility of wider applicability. It is also likely that no single technique is complete in itself. A recent review by Burset and Guigó¹⁰ has benchmarked a variety of gene structure prediction programs against a large database, and finds that on average, the predictive accuracy of most methods ranges between 60 and 70%, for eukaryotic genes. Some techniques that are presently being developed further look for homology between the derived protein sequence and existing protein databases to completely identify genes; these are currently the most accurate methods available. However, it is perhaps unreasonable to expect that any one computer algorithm – or even a combination of several of them – will predict the location of protein coding regions with perfect specificity and sensitivity. Practical wisdom would dictate that one uses some or all of the methods available to decipher a given genome⁴⁴.

As the technology for DNA sequencing becomes increasingly sophisticated, there is bound to be a virtual flood of nucleotide sequences pouring in from a wide variety of organisms. The challenge is to make sense out of this sequence information, for the ultimate answers to the mystery of life may well lie in nature's deliberate choice of certain nucleotide sequences over others.

Data coming out from sequencing projects has brought home the realization that our level of genetic ignorance is much higher than we imagined. The example of yeast, *S. cerevisiae*, is telling. An organism which one thought was genetically beaten to pulp by decades of intensive research, has actually revealed only about one-third of its secrets to molecular geneticists. From new sequencing data – and as of today all 16 chromosomes of *S. cerevisiae* have been completely sequenced – we now know that this organism houses a much greater number of potential genes than hitherto suspected. Since it is difficult to experimentally identify genes on a mass scale given the level of technology today, it is absolutely necessary to weed out noncoding sequences (especially noncoding

ORFs) so that one has fewer potential genes for experimental verification. Computational methods do provide a quick assessment of possible coding regions, and this information can help workers know where to look for probable genes and make an experimental verification of the predictions.

At the heart of it is the problem that we still do not know *all* that makes a stretch of DNA evolve into a protein-coding sequence. Only as more and more DNAs are sequenced and analysed, will the statistics will get better and we may then develop a better understanding of why some parts in DNA are coding. Mathematical methods may also provide insights into the vast amounts of non-protein-coding DNA found in complex genomes. Is this DNA truly 'junk' or is there a pattern in it which we do not comprehend? The architectural details of genomes will provide clues to the inevitable question of how life originated and evolved on this planet.

Record of prolific and indubitable acritarchs from the Lower Paleozoic strata of the Tethyan Garhwal Himalaya and age implication

H. N. Sinha, S. S. Srivastava and B. Prasad*

Department of Earth Sciences, University of Roorkee, Roorkee 247 667, India

*K.D.M. Institute of Petroleum Exploration, Oil and Natural Gas Corporation Ltd, Dehradun 248 001, India

Exceptionally well-preserved and prolific fossil acritarchs (a group of acid insoluble microfossils with uncertain affinities) have been recorded from the Shiala and Yong formations of the Tethyan Garhwal Himalaya, India. The presence of age marker forms of acritarch reveals that the Ordovician/Silurian boundary lies within the Shiala Formation and not at the contact of Shiala and the Yong formations, as was proposed by earlier workers^{1,2}.

THE Lower Paleozoic acritarchs are known from throughout the world, especially from UK, USA, Canada, Norway, Spain, Belgium, Southern Africa, Russia, China and Arabian Sahara. However, the record from India is almost negligible due to rare occurrence of marine Paleozoic sediments in the Peninsular India. Only the simple *Leiosphaerids*, sphaeromorphs, acanthomorphs

and netromorphs, are so far recorded from the marine Precambrian/Cambrian rocks of the Peninsular India (Vindhyan, Kaladgi, etc.)^{3–6} and the Extrapeninsular India (Krol belt, Lesser Himalaya, Tethys Himalaya)^{2,7–13}. In the Extrapeninsular India, the Lower Paleozoic marine sediments are well recognized in the Tethyan zone of Kashmir, Spiti and Kumaon–Garhwal Himalaya and contain a variety of invertebrate Paleozoic fossils.

The term 'Tethys' was conceived by Suess¹⁴ for a long expanse of Mesozoic seaway separating the old continental masses of the Gondwanaland in the south and Angaraland in the north. The 'Tethys Himalaya' refers to the widespread sedimentary basin to the north of the central crystalline rocks^{15,16}. The Tethyan sediments range in age from Precambrian/Cambrian to Early Tertiary¹⁷ and are rich in fossil contents. The Tethyan sediments of the Garhwal Himalaya have received

attention of geologists and palaeontologists since the initial work of Heim and Gansser¹⁸, but very little studies have been carried out on the palynological aspects so far, except that by Khanna *et al.*². They reported the occurrence of chitinozoans, melanosclerites, *Baltisphaeridium* sp. and other microfossils from the Yong Limestone formation of the Tethyan Garhwal Himalaya. Earlier, Khanna¹⁹ reported poorly preserved acritarch assemblage comprising nine genera assignable to 31 species from the Pin Dolomite sequence of Spiti valley, Himachal Pradesh.

The present acritarch assemblages (Figure 1) are recorded from the Shiala and Yong Limestone formations of Lower Paleozoic sediments exposed in and around the village Sumna (Lat. 30°40' and Long. 80°50'), which lies in the Chamoli district of Uttar Pradesh and close to the India-Tibet border (Figure 2). The altitude of area ranges approximately from 12,000 ft to 14,000 ft and the peaks are snow-covered throughout the year. The first author undertook two expeditions during August and September 1992 and 1993 to collect geological data and rock sample. The Sumna-Rimkhim mule track provides the excellent rock exposures and is the ideal section exposing a larger part of the Lower Paleozoic marine sequence. The exposed section comprises Garbyang, Shiala, Yong Limestone and Variegated formations.

Seventy-one rock samples at close intervals were systematically collected along Sumna-Rimkhim section (Figure 3). Strato-litho-petrographic column (Figure 4) has been prepared after careful computation and error correction of field observations²⁰ considering the aspects of topography, slope, traverse direction, altitude of exposed beds, lithology and petrographic characters. Thus, a total thickness of 680 m of the Lower Paleozoic marine sequence was systematically sampled along the section.

The integrated strato-litho-petrographic column shows age, name of formation (lithostratigraphic unit), thickness in meters, sample positions and names of rock types (Figure 4). Names of rock types, based on megascopic characters, have been given as limestone, sandstone, siltstone, siltyshale, etc. Subsequently, the precise and still more suitable names of rock types (lithounits), based on detailed petrographic study, have been given like mudstone (arenaceous), wackstone (bioclasts), boundstone (algal), grainstone (algal) and calcareous quartz arenite etc. as the classification of the sedimentary rocks^{21,22}.

Stratigraphy

A generalized lithostratigraphic framework of the Yong Gad section near Sumna has been given by Sinha²³ (Table 1), together with assemblage zones outlined by him.

All the 71 samples belonging to Garbyang, Shiala,

Yong and Variegated formations were subjected to standard maceration techniques for the recovery of acritarchs from its matrix. The heavy liquid analysis was done using KI, CdI₂ and ZnI. The samples of Shiala and Yong Limestone formations yielded prolific, varied and well preserved forms of fossil acritarchs belonging to subgroups sphaeromorphitae, acanthomorphitae, polygonomorphitae, herkomorphitae, diacromorphitae and netromorphitae. Rest of the samples from the Garbyang and Variegated formations have been found to be barren of acritarchs. The greenish grey, finely laminated silty-shale and the fine grained calcareous quartz arenite are the main lithounits which yielded fossil acritarchs from the Shiala Formation. Wackstone (bioclast) of the Yong Limestone Formation yielded abundant acritarchs which is greenish black.

This paper aims only to record the first prolific occurrence of acritarchs from the Indian subcontinent, in general, and from the Shiala and Yong Limestone formations of the Tethyan Garhwal Himalaya, in particular. All the slides and samples are deposited at the Department of Earth Sciences, University of Roorkee (India) for future reference.

Acritarch assemblages

The Tethyan acritarch assemblages are relatively smaller than the type species described²⁴. According to our observation, the size may be extremely variable depending on the direction of folding during burial and preservational history²⁵. A check-list of recovered acritarch species of Shiala and Yong Limestone formations is given in Table 2.

Age implication

The acritarch assemblage recovered (Figure 1) from the Early Paleozoic sequence of Tethyan Garhwal Himalaya is mainly dominated by the acanthomorphs, polygonomorphs, netromorphs, herkomorphs and diacromorphs. The occurrence of age marker forms such as *Baltisphaeridium longispinosum* var. *longispinosum*, *B. archaicum*, *B. citrinum*, *Deunffia monacantha*, *D. brevispinosa*, *D. monospinosa*, *Geron* sp. cf. *G. amabilis*, *Triangulina* sp., *Domasia trispinosa*, *Multiplicisphaeridium cladum*, *M. thusui*, *Leiofusa parvitatensis*, *L. algerensis*, *Veryhachium* sp. cf. *V. wenlockium*, *Stellichinatum celestum*, *Dactylofusa* sp. cf. *D. oblancae* and *Oppilatala? indianae* suggest Late Ordovician to Late Silurian age for the sediments exposed along the Sumna-Rimkhim section.

The sediments of the Shiala Formation yielded dominant to common occurrence of *Ordovician nudum*, *Multiplicisphaeridium ornatum*, *Veryhachium longispinosum*,

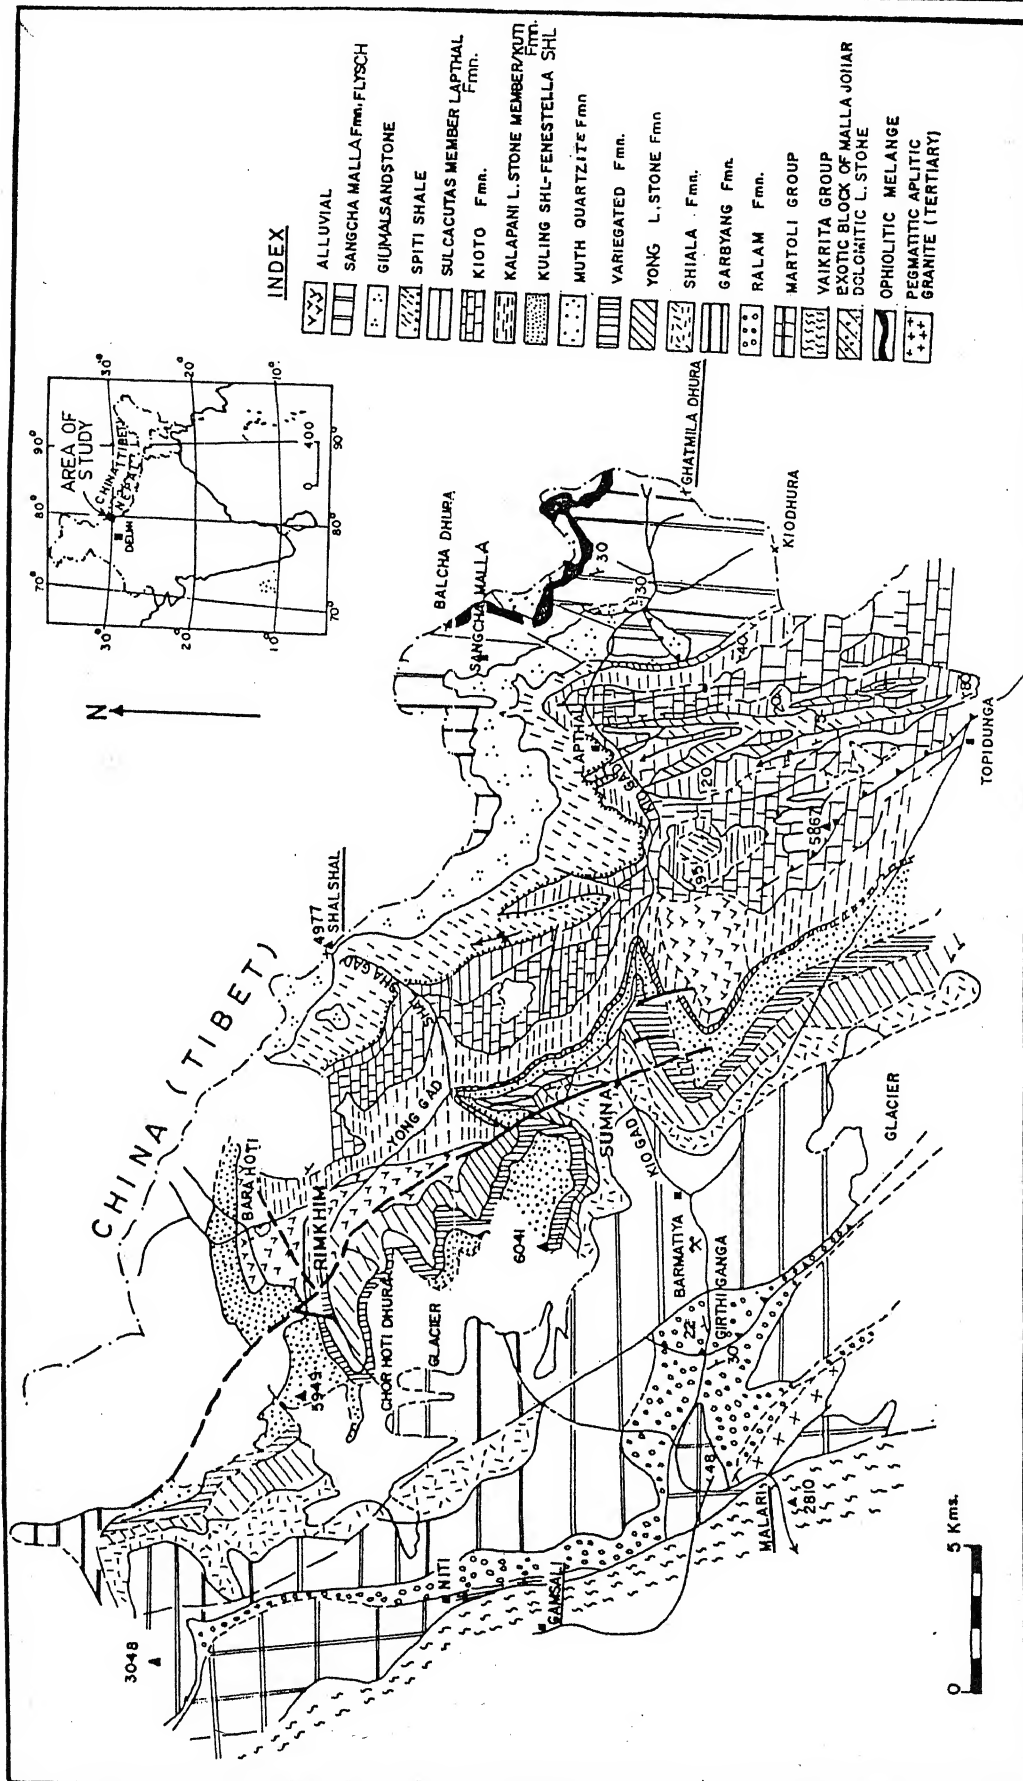

Figure 2. Geological map of the Malari-Lapthal area of Tethyan zone of the higher Garhwal Himalaya, India (A. K. Sinha, 1985).

Filisphaeridium henryi, *Neoverhachium* sp., subdominant presence of *Michrhystridium robustum*, *M. parinconspicuum*, *Acanthodiadrodium simplex*, *Solisphaeridium nanum*, *Baltisphaeridium citrinum* and *Coryphidium miladum* along with restricted occurrence of *Baltisphaeridium longispinosum* sub sp. *delicatum*, *B. archaicum*, *B. longispinosum* var. *longispinosum*, *B. bystrentos*, *Deunffia monacantha*, *D. monospinosa*, *D. brevispinosa*, *Domasia trispinosa*, *D. algerensis*, *Geron* sp. cf. *G. amabilis*, *Leiofusa parvitatis*, *Multiplicisphaeridium cladum*, *M. thusui* forms which are globally restricted to Caradocian to Wenlockian age^{28,30,33,36,37,40,44,62,75,76,80-91}.

Therefore, Caradocian to Wenlockian age is assigned to the Shiala Formation.

The Yong Limestone Formation yielded marker acritarch species, such as, *Leiofusa berneseage*, *Oppilatala?*

indianae and *Multiplicisphaeridium variabile* which have been described from Ludlovian sediments of various places^{28,34,45,80,92,93}. Therefore, Late Silurian age (Ludlovian) is inferred for the Yong Limestone Formation.

The sediments overlying the Yong Limestone Formation belong to the Variegated Formation and are observed to be devoid of acritarchs. However, the Muth Quartzite section which overlies the Variegated Formation has yielded rich assemblages of brachiopod (*Pentamerifera* sp.) of the Late Silurian age⁹⁴. The record of Late Silurian brachiopod in the top horizon of the Muth quartzite sequence suggests Ludlovian age for the Variegated Formation.

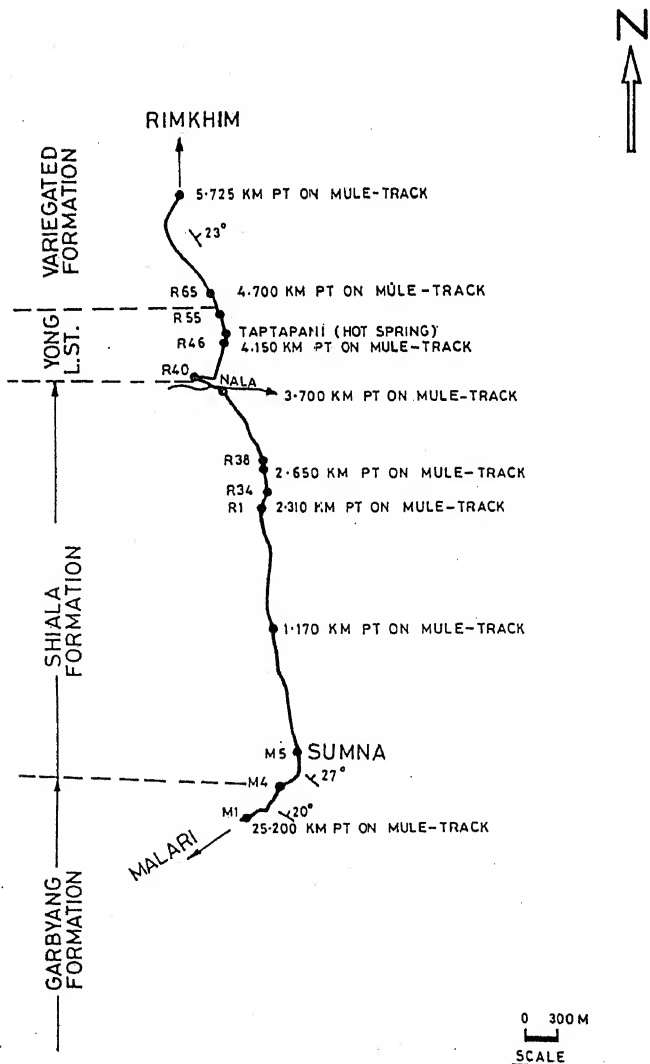

Figure 3. Sumna-Rimkhim mule-track section showing location of samples.

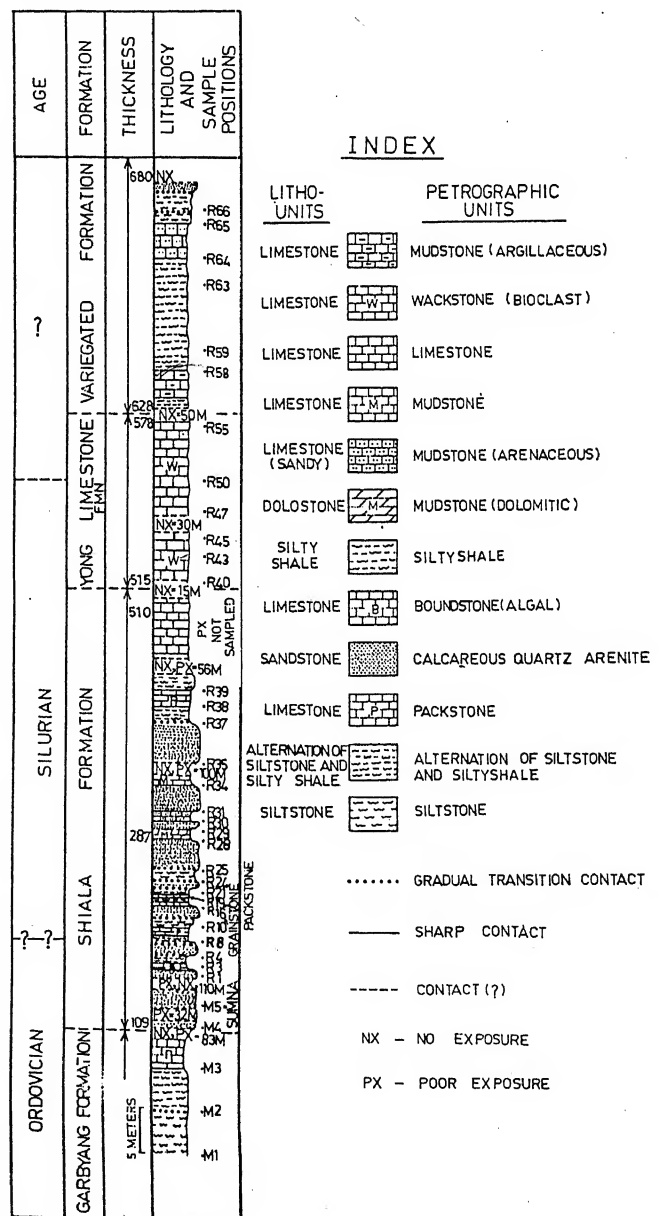

Figure 4. Integrated strato-litho-petrographic column of Sumna-Rimkhim section along the right bank of Yong Gad Valley showing sample positions.

Table 1. Generalized lithostratigraphic framework (Sinha, 1989)

Time unit	Lithounit	Broad lithology	Assemblage zones
Silurian	Variegated Formation	Purple l.st and shl. with bands of quartzite	<i>Strophonella</i> zone
	Yong Limestone	Green nodular biohermal and biostromal l.st.	<i>Calostylis</i> zone
Ordovician	Shiala Formation	Grey to pinkish s.st. quartzite, l.st.	<i>Rafinesquina</i> alternate zone
		Alternate bands of s.st. and shl.	<i>Monotrypa</i> zone
		Alternate bands of greenish shl. and biostromal l.st., splintery shl. with arenite	<i>Rafinesquina aranea</i> zone, <i>Orthis testudinaria</i> zone
	Garbyang Formation	Green needle shl. with occasional limestone

	4. <i>Impluviculus</i> ⁵⁷ , <i>I. sp. cf. I. stellum</i> ³⁹		

All the genera/species are extracted from sample No. R-8-siltyshale, unless mentioned otherwise.

Discussion

The acritarch studies of the Sumna–Rimkhim section of the Tethyan Garhwal Himalaya have provided fresh impetus to the stratigraphy of this region and revised the earlier date assigned to the Shiala Formation.

The earlier work^{2,23} suggests that the Ordovician–Silurian boundary lies within the lower part of the Yong Limestone Formation. However, the recognition of stratigraphically important acritarch species suggests that the Ordovician–Silurian boundary lies within the Shiala Formation at 2.320 km pt on the Sumna–Rimkhim mule track section (Figure 3) and at the sample position [No. R-8 (Figure 4)]. This shows that the lithostratigraphic boundary may not coincide with the biostratigraphic boundary.

ACKNOWLEDGEMENTS. We thank Mr K. Chandra and Dr J. Pandey for assistance at the ONGC Laboratory, Dehradun; Mr James Peters, Dr B. K. Singh, Mr P. K. Bhatnagar, Mr C. M. Misra, Mr P. N. Kapoor, Mr B. S. Pundeer and Dr Arun Kumar of the ONGC for help in analyses and discussion; Mr Rajesh Chauhan for helping in palynological slide preparation. Mr Sanjay Sood of GNDU, Amritsar is also acknowledged for valuable help provided during preparation of manuscript.

We also thank the Defence Ministry (Govt of India) for allowing HNS for field work and photography. Financial support was received from the UGC, Govt of India, to HNS in the form of fellowship during his doctoral programme.

Received 16 October 1995; revised accepted 13 May 1996.

JAWAHARLAL NEHRU CENTRE FOR ADVANCED SCIENTIFIC RESEARCH

Jakkur, Bangalore 560 064

VISITING FELLOWSHIPS

Advt. No. 11/96

17 June 1996

The Centre announces a programme to enable research scientists and engineers in educational institutions, R&D laboratories, etc., to spend up to 2-3 months in association with a **member of the Faculty of the Centre**. The Faculty members of the Centre are located in different leading institutions of the country and the actual place of work will therefore be decided on the basis of the research interests of the Visiting Fellow, in consultation with the concerned member of the Faculty in the area. The Visiting Fellow would be paid a consolidated honorarium of between Rs 3,500 and Rs 7,500 per month during the period, in addition to round trip train fare between his place of work and the institution of the Faculty member.

Research scientists and engineers in educational institutions, R&D laboratories, etc., with an interest in the broad areas of **life sciences** (molecular and developmental biology, biotechnology, genetics, ecology, behaviour, biomedical research), **chemical sciences** (solid state chemistry, inorganic and physical chemistry, organic chemistry), **physical sciences** (theoretical physics, mathematical physics, astronomy and astrophysics, experimental areas), **engineering sciences** (chemical, metallurgical, computer science, fluid mechanics), **mathematics** or **atmospheric sciences** are invited to apply.

Application forms may be obtained by writing to the Coordinator of the Centre in Bangalore for Fellowships during 1996-97.

Last date for receipt of completed application form: **30 August 1996**

Tumour-promoting diterpene esters of the plant family Euphorbiaceae

Rajiv R. Upadhyay

Upadhyay Cancer Research Institute, Campus Kothi Kake Babu, Deo Kali Marg, Faizabad 224 001, India

The plants of the family Euphorbiaceae produce highly skin inflammatory, caustic, irritant latex and seed oil. This is mainly due to the presence of various long chain esters of saturated fatty acids, attached at C-12 and C-13 positions of the diterpene phorbol and at C-3 position of ingenol moieties. These diterpene esters are strong tumour promoters in Berenblum's experiment and are well established as carcinogens. The use of croton oil for fish killing in small ponds and consumption of bitter honey, contaminated with ingenol esters, play positive role in exacerbating the overall process of carcinogenesis, among the population exposed to these tumour promoters. This observation is well sustained from epidemiological studies.

The earliest, and probably the most significant biological effect of croton oil, which is obtained from the seeds of *Croton tiglium* L., belonging to the family Euphorbiaceae and growing as leafy shrub in India, Ceylon, Philippines, Mauritius and China, was demonstrated by Berenblum in 1941. The weekly application to the interscapular skin of mice of acetone solutions of benzpyrene and this oil or benzpyrene and croton resin, caused significant augmentation of carcinogenesis, in comparison to that observed with benzpyrene solution alone¹. Although such cocarcinogenic activity had previously been shown with oleic acid², these experiments showed that croton oil was the most potent naturally occurring cocarcinogen known.

An important step towards understanding the actions of croton oil was the observation by Mottram, that benzpyrene need only be applied once in a sub-manifestational dose to prepare the skin so that subsequent multiple applications of croton oil can elicit tumours³. Based on these observations Berenblum and Shubik⁴ proposed two-stage theory of chemical carcinogenesis. Further refinement of this experiment lead it to be known as Berenblum's experiment⁵.

The initial sub-threshold dose of the carcinogen such as benzpyrene induced an irreversible initiating process, resulting in the formation of latent tumour cells. Subsequent repeated applications of croton oil or *Euphorbia* lattices, caused an epicarcinogenic or promoting process, which enabled such latent tumour cells to develop into malignant cells.

The term cocarcinogenicity is a general one which refers to all forms of augmentation of tumour induction.

The phenomenon can arise in many ways, including additive, synergistic, preparative or incomplete carcinogenic action⁶. Tumour promoters are, thus, only one type of cocarcinogen and have been classified as incomplete carcinogens since they can complete the process begun by the initiator⁷⁻⁹.

It has been demonstrated experimentally that the information, 'potential tumour cells' generated by the initiator, persist in the target tissue for a very long period, i.e. for at least 2/3 to 3/4 of the average life span of mice¹⁰. Therefore it is reasonable to assume that the growth of 'potential tumour cells' remains under the control of the surrounding cells. If, however, after initiation the target tissue is treated repeatedly with promoter, for example, croton oil or its most active constituent: 12-tetradecanoyl-phorbol-13-acetate (TPA)⁷; the growth of the potential tumour cell is prompted to yield papillomas. These papillomas become malignant even after some time due to the inherent tendency. Therefore, in addition to the stages of tumour initiation and promotion, a third stage called tumour progression, was also postulated for mouse skin¹¹⁻¹⁴ (Figure 1).

TPA (Figure 2 b) and other 12,13-diester of diterpene phorbol represented only 50% of the entire phorbol content of croton oil and the rest of the phorbol was present in the hydrophobic portion as unidentified form of phorbol-12,13,20-triester. This was demonstrated for the first time with the isolation of a new 'cryptic irritant and cocarcinogen' from the seed oil of *Croton sparciflorus*. This new substance was found to be

Figure 3. Ingenol and its esters isolated from *Euphorbia* species growing in Azarbaijan province of Iran.

acid attached to position 20 of phorbol moiety (Figure 2 c) to be released selectively to yield corresponding highly active and irritant 12-dodecanoyl-phorbol-13-acetate, which is a strong tumour promoter on mouse back skin experiment. It is likely that such activation can probably take place in tissues exposed to 12,13,20-triesters¹⁵.

From the skin irritant and purgative seed oil of *Euphorbia lathyris* L. and from its highly skin inflammatory latex, esters of another diterpene, which is reminiscent of diterpene phorbol, called ingenol, have been isolated. Out of these esters ingenol-3-hexadecanoate had been found to be skin irritant and tumour promoting in Berenblum's experiment¹⁶. Further, from the skin-inflammatory and tumour promoting latex of *Euphorbia lactea*, which causes severe dermatitis and inflammation to skin, to human and animals alike, hydroxylated derivative of ingenol, called 16-hydroxy ingenol, had been isolated¹⁷ (Figure 3 b, c). In a standard experiment on the preshaved and preinitiated back skin of NMRI mouse, 0.1 μm of 7,12-dimethyl benzantracene in acetone produced squamous cell carcinoma¹⁷ after 28 weeks.

The caustic, skin irritant and tumour-promoting latex of *Euphorbia serrata* L., which grows profusely around Tabriz, capital of Azarbaijan province of Iran, and the latex of *Euphorbia seguieriana* Neck. obtained from the same region, were found to contain parent diterpene ingenol^{18,19}. However, in tumour-promoting experiments on preshaved back skin of NMRI mouse initiated with dimethyl benzantracene in acetone as usual, the latex preparation of *Euphorbia serrata* produced squamous cell papilloma within a short span of 16 weeks, due to the presence of ingenol-3-palmitate in the latex sample²⁰ (Figure 3 d), whereas the latex preparation of *Euphorbia seguieriana* Neck. produced squamous cell papilloma within 14 weeks, on the back skin of NMRI mice.

The plant of *Euphorbia esula* L. is known to cause sheep mortality and produces inflammation with the loss of hairs from the feet of the horses. The latex causes blistering with severe irritation if allowed to remain on the skin and it can lead to partial blindness if dropped into the eyes²¹. From this latex highly skin inflammatory unsaturated Δ -2,4,6,8,10-pentene-tetradecanoic acid, esterified at C-3 position of diterpene ingenol has been isolated. However this ingenol ester is nontumour promoting²² in mouse back skin experiments. From this latex another ester of ingenol, though less irritant yet tumour promoting on mice skin, was found to be ingenol-3-dodecanoate (Figure 3 e). This produced squamous cell papilloma in a short duration of 20 weeks²². *Euphorbia striatella* Boiss, which not only contained highly inflammatory latex but has various medicinal properties, was found to contain highly skin irritant, but nontumour promoting ingenol- Δ -2,4,6-decatrienoate²³. In tumour-promoting experiments on back skin of NMRI mice, the latex promoted the formation of

RESEARCH ACCOUNT

squamous cell papilloma; due to the presence of ingenol-3-decanoate, within 22 weeks²³ (Figure 3f). *Euphorbia virgata*, which grows profusely in the Saidabad area of Tabriz, have been found to contain highly skin irritant latex, from which non skin irritant esters of diterpene ingenol, such as ingenol-3-phenyl acetate, and ingenol-3-benzoate were isolated. However, the irritant activity of the latex was represented by ingenol-3-tiglate and ingenol-3-(2)-phenyl decanoate. Out of these two ingenols 3-(2)-methyl decanoate (Figure 3g) was found to promote the process of tumour formation on mouse back skin²⁴. From another plant, viz. *Euphorbia megalantha* Boiss, the latex of which is moderately skin inflammatory; ingenol and a new diterpene derivative of ingenol called 4-deoxy ingenol, has been isolated²⁵. The structure of this ingenol derivative is shown in Figure 3h.

In continuation of our studies on skin irritant and tumour-promoting diterpene esters from the plants of *Euphorbiaceae* family, growing in Azarbaijan province of Iran²⁶, out of the 19 species, with curious exception of *Chrozophora tinctoria* Jass., all species were found to contain no cryptic irritant, but short chain esters of diterpene ingenol only²⁷. Long chain esters were identified as usual and for the short chain esters of ingenol, gas chromatographic techniques were found highly suitable²⁸, after these were purified by column and thick layer chromatography in the standard way^{29,30}.

It has also been shown that ingenol-3,5,20-triacetate (Figure 3a) which is totally ineffective as tumour promoter and weakly skin irritant produces in initiation promotion experiment lung adenoma in NMRI mice instead³¹. The seed oil of *Croton tiglium* L. is used by natives in India, for fish killing in small ponds, which contain mostly mud dwelling, air breathing, hardy fish *Heteropneustes fossilis*, along with other fish species³². The other plants of *Euphorbiaceae* are also employed by the tribals of Southern Rajasthan for stupefying the fish in ponds³³. These facts prompted us to take up the freshwater fish, *Heteropneustes fossilis*, as a model to study the process of liver carcinogenesis in this species.

Further, the seed oil of the plants of the family *Euphorbiaceae* growing around Faizabad was screened for its toxic effect on *H. fossilis*, and among all oils tested, the oil of *Croton tiglium* was found to be highly toxic to this fish species³⁴. Interestingly, the acetone preparations of some latex sample of the *Euphorbia* species growing in abundance around Ayodhya-Faizabad, showed strong anti-termite effects³⁵.

It has been demonstrated that administration of 0.1 μ M of 7,12-dimethyl benzantracene in tricaprylin, pro-os to this fish, only once, followed by oral administration of croton oil in tricaprylin repeatedly, triggered the formation of marked basophilia in the liver³⁶. The formation of basophilia along with other changes in the

liver were also noted when initiation has been done as recorded above and promotion was performed by pricking the liver of this fish repeatedly at fixed intervals³⁷. Various cellular changes such as hyperplasia, thickening of cell wall, loss of cytoplasm, vacuolization, nuclear displacement, and very high degree of mitosis coupled with marked basophilia, which was indicative of preneoplasia leading to hepatocellular carcinoma formation³⁸, were noted, when these fish were exposed under suitable conditions to 7,12-dimethyl benzantracene (in high doses)³⁹, 2-acetyl aminofluorene, urethane and methyl carbamate-1-naphthol⁴⁰. The Godrej hair dye, permanent black, liquid preparation, produces carcinogenic symptoms in the liver of this fish⁴¹, whereas edible dyes such as Sun Set Yellow and Brilliant blue, induce degenerative changes in the liver of *Heteropneustes fossilis*⁴². Interestingly, some synthetic strained ring compounds, having marked pharmaceutical applications, were also found to induce marked basophilia in the liver of *H. fossilis*⁴³, as did HCH (ref. 44).

It is now well established that tumour promoters make up a group of compounds largely differing from one another in chemical structure that, though by themselves non-carcinogenic, enhance the development of malignant transformation in carcinogen-initiated parenchymal and stromal cells of various organs⁴⁵. Tumour promoters also evoke a pleiotropic-hyperplastic response and several phenotypically neoplastic features in normal, i.e. non-initiated cells⁴⁶. The complex operative biological mechanism of such agents and the relation of their manifold biological effects to the actual promotion of neoplasia are the current subjects of intense investigations. Several early metabolic events, like the induction of a pro-oxidant state and of enzymatic changes at the plasmalemmal level, the stimulation of metabolism of phospholipids and of arachidonic acid, the biosynthesis of polyamines etc. seem to play a relevant role in the enhancement of the responses triggered by tumour promoters⁴⁷.

The transmembrane Ca^{2+} fluxes and events requiring the activation of Ca^{2+} binding sites, of calmodulin modulated enzymes and of ubiquitous Ca^{2+} activated phospholipid dependent protein kinase-C seemingly play a key role in the control of normal and abnormal cell proliferation and also of differentiation and functioning⁴⁸⁻⁵². It is a well-established fact that TPA and tumour promoters of marine origin such as teleocidene, lyngbyatoxin-A and aplysiatoxin induce tumour promotion through the activation of protein kinase-C. In this process the amounts of phosphoproteins increased and then expression of early response genes such as *C-fos* and *C-jun* was initiated⁵³.

Thus, the early event of tumour promotion is the increase of phosphoproteins and these act as signals for gene expression resulting ultimately in induction of clonal growth of the initiated cells^{54,55}, and are possibly

involved in the inhibition of apoptosis in tumour promoting phase⁵⁶.

Although induction of Epstein-Barr virus by these tumour promoters of phorbol and ingenol type is well established⁵⁷⁻⁵⁹, procedure for detection, but the development of basophilia in the liver of *H. fossilis*, can also be used for detecting the presence of these tumour promoters in polluted waters^{60,61} on one side and on the other it indicates the unsuitability of such fish for human consumption, as has been the case with bitter honey, collected from Saidabad area of Azarbaijan. In Saidabad area, the plants of *E. sigueriana* grow profusely and honey bees collect the nectar from the flowers. This honey tastes bitter, as it is contaminated with the tumour promoters of ingenol type⁶². The consumption of such honey appears to be the main cause for increased risk of oesophagus cancer, in hilly regions of Azarbaijan province of Iran, a fact well sustained from the epidemiological studies^{62,63}.

It has also been shown that the high incidence of oesophageal cancer on the Caribbean island of Cura-cao is mainly due to the consumption of Welensali-tea, made from *Croton flavens* leaves from which phorbol derivatives exhibiting tumour promoting activity in the oesophagus have been isolated⁶⁴. These tumour promoters contaminate indirectly milk and meat when the livestock food get mixed with the plants of Euphorbiaceae⁶⁵.

Likewise, environmental carcinogens other than those emanating from the Euphorbiaceae family, include algal microcystins, which are known to contaminate the ditch water and enhance the chances of liver cancer in certain parts of People's Republic of China^{66,67}, indicating the role these tumour promoters play in exacerbating the total carcinogenic load of the environment.

RESEARCH ARTICLES

Submarine terrace limestones from the continental slope off Saurashtra–Bombay: Evidence of Late Quaternary neotectonic activity

V. Purnachandra Rao and M. Veerayya

National Institute of Oceanography, Dona Paula, Goa 403 004, India

Bathymetric and shallow seismic data from the continental slope off Saurashtra–Bombay indicate wide submarine terraces at 130, 145 and 170 m and reefal structures at 320–360 m water depths. 10 cm thick slabs of limestones are recovered from the 130 m depth terrace. Some of these limestones consist of thin micrite layer on the top and a sandy layer below and others are similar to calcarenites. They contain > 95% aragonite and minor high- and low-magnesium calcite. Acicular aragonite cements occur as isopachous crusts. Dissolution and clotting of aragonite needles and drusy calcite in the interstices indicate cementation of the limestones at intertidal conditions. The age of the limestones is 11,900 years BP. These imply that the 130 m depth terrace was at intertidal depths at about 12,000 years BP. The eustatic sea-level, however, was at –90 m at 12,000 years BP. This disparity suggests neotectonic activity and subsidence by about 40 m on the Saurashtra–Bombay region some time after 12,000 years BP.

SUBMARINE terraces are important geomorphic features on the continental margins and may record former sea-levels¹. Submarine terraces have been reported^{2–4} on the western continental shelf of India between 35 and 115 m and also between 115 and 170 m water depths on the continental slope off Saurashtra–Bombay⁵.

Saurashtra was tectonically unstable during the Pleistocene^{6–9}. The eustatic sea-level¹⁰ low during the Last Glacial Maxima (LGM) was only –120 m. The deeper terraces may therefore have implications to neotectonism and Quaternary sea-level changes. We report here the investigations on the limestones from a 130 m depth submarine terrace off Saurashtra–Bombay and provide evidence of Late Quaternary neotectonic activity, hitherto unknown from the western offshore.

Materials and methods

During the cruise 150 of the *R. V. Gageshani*, bathymetric and shallow seismic data were collected from the continental shelf and slope off Saurashtra–Bombay. Sediment and limestone samples were collected with a Peterson grab (Figure 1). Mineralogy of the representative samples was determined by X-ray diffraction. Freshly broken surfaces of the limestone fragments were examined under a scanning electron microscope (JEOL T20). Radiochemistry of the limestones was carried out at the Hydrogeology and Isotope Geochemistry Laboratory, University of Paris, Orsay. Polished and thin sections of the limestones were studied under petrographic microscope.

Results

Geomorphology

The width of the continental shelf off Saurashtra ranges from 110 to 200 km. However, in the southern part, it is about 160 km wide and the shelf break occurs at 100 m water depth. Well developed 1.5 to 2.0 km wide terraces occur at 130, 145 and 170 m water depth on the continental slope (Figure 2 a and b). Several seismic profiles across the shelf and slope off Saurashtra-Bombay indicate that these terraces are major topographic features on the upper continental slope. A 15–20 m thick acoustically transparent clayey sand layer occurs landward of

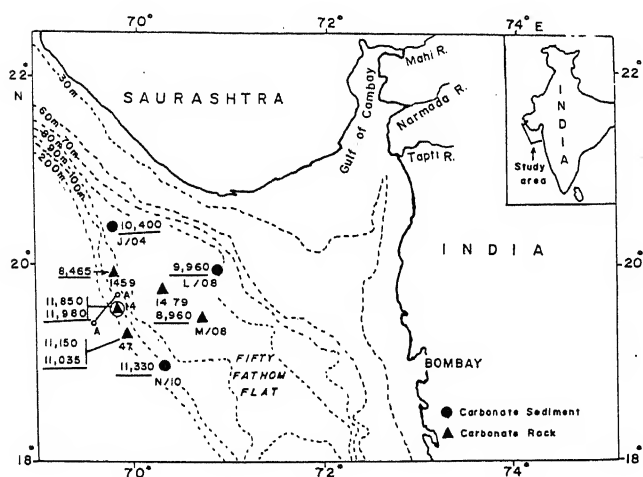

Figure 1. Sample location map (Saurashtra-Bombay). Sample collected at station 14 has been studied in this paper. Other radiocarbon dates of the samples (available in this area) are also shown and underlined. Line A-A' indicates the position of the shallow seismic (3.5 kHz ORE subbottom) profile shown in Figure 2 a.

Figure 2 a. Seismic profile at the shelf break-upper continental slope showing the terraces (T) with terrigenous clayey sand zone on landward and reefal structures on seaward (see Figure 1 for location A-A').

the terraces and pinches out at 120 m depth (Figure 2 a, b). Terraces show strong acoustic reflections in seismic profiles, may be due to the exposure of relict carbonate sands and limestones. Further seaward 2 km wide and 25 m high massive reef was found at depths between 320 and 360 m (Figure 2 a).

Mineralogy and radiochemistry of the limestones

The limestones recovered from 130 m depth terrace are 10 cm thick slabs; their lower surfaces are flat and light brown and upper surfaces contain 1 cm diameter macroborings, serpulid encrustations (Figure 3 a) and ferruginized coatings. Associated sediments consist of 1–5 cm size pelecypod shells, limestone fragments and a few coral pieces. The limestones contain > 95% aragonite and minor high and low-magnesium calcite. The radiocarbon ages of the micrite-dominated and pellet-rich limestones are $11,980 \pm 185$ BP and $11,850 \pm 210$ BP and $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$ values of these two limestones are +4.03‰ and +3.75‰ and +1.66‰ and +1.64‰, respectively.

Petrology of the limestones

Polished sections of some limestones show large borings filled with fine-grained carbonate mud (Figure 3 b) and in others dense and loosely cemented areas leading to different textures (Figure 3 c). Some other limestones contain abundant shell fragments in their upper portions. The limestones can be divided into micrite-dominated and pellet-rich types.

Micrite-dominated limestones consist of thin micrite-dominated layer on the top and sandy layer below. The micrite layer is laterally discontinuous and consists of trapped carbonate debris, partly to completely micritized algae (Figure 4 a, b) and a few pellets. Pellets are abundant in the sandy layer and cement is again micrite. Patches of micrite (Figure 4 c) consisting of oolite aggregates, cemented intraclasts and terrigenous particles are present. Pellet-rich limestones are calcarenites. Pellets (Figure 4 d) are the most abundant constituents followed by oolites, shell fragments, algal fragments with minor echinoids and benthic foraminifers. Many are mature oolites with several well developed concentric laminae. The nuclei are mainly pellets, sometimes skeletal fragments. Some oolites are bored and infected by microbial activity and their concentric laminae are riddled with a discontinuous zone of sparry calcite (Figure 4 e).

Boring cavities often impart a porous fabric to the rock (Figure 4 d). Some of the cavities are filled with terrigenous clay. Carbonate intraclasts and/or quartz and clay aggregates (Figure 4 e) commonly occur in the intergranular spaces. Acicular aragonite forms dense isopachous crusts around grains (Figure 4 f). Aragonite

Figure 2b. Seismic profile showing submarine terraces (T) and pinching out of clayey sand zone on landward of the terrace from the upper continental slope off Saurashtra-Bombay. Arrow indicates approximate location of the limestone sample on the terrace which is 1.5 km south of the profile. M-multiple, (see Figure 2a for location AA-AA').

Figure 3a. Hand specimen of a limestone showing boring cavities and thickly encrusted serpulid worm tubes; (b, c) polished sections: b, the boring cavity filled with aragonite muds; c, dense and loosely cemented patches in the limestones, leading to different textures.

cements are locally dissolved and replaced by the development of calcite spar and their growth was apparently terminated before the introduction of clay in the pores (Figure 4f). Peloidal micrite cements are rare.

SEM studies on limestone fragments indicate that micrite is an aggregate of 1–2 μm globular carbonate particles (Figure 5a). Needle aragonite fringe cements (Figure 5b) are abundant. Matting of aragonite needles leading to drusy calcite (Figure 5c), dissolution of aragonite needles and the formation of calcite aggregates (Figure 5d), peloids consisting of mixture of micrite and aragonite needles and spherical aggregates of micrite are present. Globular aggregates of calcite occur within the boring cavities (Figure 5e) and sometimes attached to microbial filaments within the interstices (Figure 5f).

Discussion

Environmental conditions during sediment accumulation and cementation

Abundant shell fragments and pellet-rich sediments with some oolites in some limestones indicate high energy conditions prevailed during sediment accumulation. Colonization of both algae and lichens can produce laminated crusts on the upper surfaces of the rocks. Lichen produced crusts are, however, amorphous¹¹. The laminated micrite crusts with trapped detritus and algal material (Figure 4a, b) may therefore suggest algal colonization by trapping and binding activity and their subsequent calcification to micrite. Algally formed micrite laminations in

Figure 4 a–c. Photomicrographs (plane polarized light) from micrite-dominated limestone. *a*, showing distinct ferruginised micrite-dominated layer on the top and light brown micrite layer below; *b*, partly micritized algal body; *c*, a micrite patch with cemented intraclasts; *d–f*, photomicrographs from pellet-rich limestones (plane polarized light); *d*, pelletal grains in aragonite cements, porous fabric is due to the boring activity of algae; *e*, oolites which are infected by microbial activity showing obscured laminae; *f*, aragonitic isopachous rim cements, porefilling aragonite cements are being replaced by calcite mosaics and terrigenous clays and quartz in the interstices.

Figure 5a-e. *a*, Micrite matrix showing that it is an aggregate of 1-2 μm size globular particles; *b*, acicular aragonitic fringe cements; *c*, clotted aragonite needles; *d*, a globular calcite aggregate on top of aragonite needles; *e*, globular calcite in boring cavities, several fungal filaments on aragonite matrix can also be seen; *f*, enlarged portion of 'e' showing filaments which are irregularly branched.

supratidal limestones are thicker and laterally more continuous than those in intertidal conditions¹². So the thin, laterally discontinuous micrite laminations (Figure 4a) in some limestones and intraclasts, shell and pellet-dominated sediments with mature oolites in others probably suggest that the sediments were accumulated in intertidal conditions. Detrital material (Figure 4f) most probably washed onto these sands and subsequently filtered down into the pores under agitating conditions.

(i) Endolithic algae/fungal activity is evident in these limestones by the porous fabric (Figure 4d), microbially infected oolitic laminations (Figure 4e), algal borings and fungal filaments (Figure 5e,f). Endolithic algae are abundantly photosynthetic and they bore intensively in nearshore zones¹³.

(ii) Although micrite is abundant in both subtidal and intertidal limestones^{14,15}, it is mostly high-magnesium calcite in submarine cemented limestones¹⁶. The micrite reported here, however, is aragonite.

(iii) Four types of cements exist: thinly laminated micrites (Figure 4a), dense patches of micrite (Figure 4c), acicular aragonite (Figures 4f, 5b) and peloidal cements. These cements are further complicated by subsequent superposition of other cements. Replacement of pore filling aragonites by calcite (Figure 4f), clotted aragonite needles (Figure 5c) and calcite aggregates on top of aragonite needles (Figure 5d) indicate that initially formed aragonitic cements were subsequently replaced by drusy calcites. Similar cement fabrics were reported¹⁷⁻¹⁹ in intertidal limestones and beachrocks. The formation of clotted aragonites and drusy calcites perched on aragonites was attributed to the high degree of super saturation in the pores of sands at intertidal conditions¹⁷. Micrite patches enclosing terrigenous particles suggest that allochthonous micrite filled the boring cavities. These four types of cements cause different textures in the rock (Figure 3b, c), a feature generally observed in beachrocks.

(iv) Submarine cemented limestones consist of aragonite

skeletal components replaced by high-magnesium calcite and abundant peloidal high-magnesium calcite cements^{16,20–22}. In contrast, the limestones studied here contain minor high-magnesium calcite, rare peloidal cements and unaltered skeletal aragonites. In view of (i) to (iv) we suggest that these limestones were cemented at intertidal conditions.

Relationship of terrace limestones with sea-level changes

The age and depth relationship of the limestones suggest that intertidal conditions existed at 130 m depth terrace at about 11,900 years BP. Contrastingly, the glacio-eustatic sea-level¹⁰ was at –90 m at about 12,000 years BP. Three possibilities exist to explain this disparity:

(i) The limestones might have been transported from shallow shelf. This is unlikely as a terrigenous clayey sand zone (15–20 m thick) exists landward of the terrace (Figure 2a, b). The clay in the interstitial pores of the limestones (Figure 4f) may have originated from this clayey sand zone. Moreover, the limestones are from a wide terrace and the constituents in limestones and in unconsolidated sediments of the terrace are similar.

(ii) Incorporation of modern carbon and replacement of aragonite by calcite may give younger ages of limestones than the actual. This is also unlikely as the dates given here were corrected for modern industrial carbon and, calcite content (low and high-magnesium calcites) is <5% and low-magnesium calcite that replaced the aragonite is a small part within the 5% which may not have major influence on the given dates.

(iii) This part of the continental margin may have subsided after the limestones were formed. It is more likely as the terraces occur at depths more than 120 m (eustatic sea-level low during the LGM–18,000 years BP). Vadose diagenetic limestones of Holocene age on the Fifty Fathom Flat^{23,24}, missing data for the period younger than 8,300 years BP from the offshore and tidal mud flats of Early Holocene age at +8 to +10 m above the present sea-level in the coastal Gujarat and Maharashtra^{25,26} probably support neotectonic activity in this region.

The sea-level rise after 11,900 years BP was 130 m on this margin. The eustatic sea-level rise¹⁰ after 12,000 years BP was only 90 m. This suggests that some time after 11,900 years BP, the margin may have subsided by about 40 m. This subsidence could be due to the overburden of Indus-borne sediments accumulated on the continental slope and in the adjacent Arabian Basin as also suggested by Whiting *et al.*²⁷.

Petrogenesis of granitic rocks of low- to high-grade transition zone of Krishnagiri, Dharmapuri District, Tamil Nadu

C. G. Chandrasekaran and S. Subramanian*

Department of Geology, Presidency College, Madras 600 005, India

*Z 277 (57C), V Avenue, Anna Nagar, Madras 600 040, India

The granitic rocks of low- to high-grade transition zone of Krishnagiri are distinctly grey coloured, exhibiting a clear gneissic banding with predominant tonalite-granodiorite composition. Ubiquitous occurrence of amphibolite enclaves in the granite suggests a genetic link between the two. The rocks are composed of quartz, plagioclase and subordinate amounts of orthoclase and microcline as light coloured minerals with hornblende and biotite as mafics. Chemically, these granitoids belong to moderate- to high-alumina type and metaluminous granite with average A/CNK value being less than unity. Magmatic parentage is discernible from the behaviour of many major and trace elements. Abundances of certain elements like TiO_2 , MgO, Sr and Ni indicate a basic source. REE data support the partial melting of garnet-bearing amphibolite source in the evolution of these granitoids. The I-type characteristics and low Rb/Sr ratios suggest that the amphibolite source is possibly derived from an enriched mantle/lower crust with mafic constituents. The mineralogy and petrochemistry match well with the granites of IAG + CAG affinity.

THE Archaean rocks of India are a complex suite, comprising greenstones, low, and high-grade gneisses and granites with polyphase and polygenetic characters and ages ranging from 3300 m.y to 2500 m.y (ref. 1). On the basis of the extensive study on these rocks, it is now generally understood that they have complicated plutono-metamorphic history, heterogeneity of petrochemical composition, time-space distribution, obliterated original structures due to subsequent deformations and metasomatism. Granitic rocks, constituting a major component of the Archaean, have also undergone the tectonics. Some petrologists², believe that most of the granitic rocks occurring in Precambrian Cratons and Mobile Belts are better indicators of the crustal processes and compositions as these rocks are considered to owe their evolution to conditions of high temperature and abnormal crustal activity prevailing during orogenic events. Therefore, more emphasis is placed on the investigation of the Archaean granitic rocks in recent years to probe into their probable precursors. The studies, so far, carried out on the litho-units of Transition Zone in

Dharmapuri District mainly concentrated on their metamorphic grade of formation³⁻⁶. The present study constitutes a detailed account of the granitic rocks occurring in the transition zone of Krishnagiri.

Field setting

The granitic rocks, occurring in and around the transition zone of Krishnagiri (Figure 1), are distinctly grey-coloured, exhibiting a clear gneissic banding with dominant tonalite-granodiorite composition and subordinate occurrences of granite (s.s.). Mostly, they are medium-grained with occasional fine and coarse-grained varieties. The gneissic banding, often, exhibits contortion in compositional layering which gives rise to small scale close folds with parallel fold axes. Abundant amphibolite enclaves with different shapes and sizes are present which depict a structural pause with the surrounding granitoids and are regarded as possible relics of the older crust⁷. The last phase of the igneous activity in the area is represented by the profuse development of dolerite dykes cross cutting three granitic rocks dominantly in WSW-ENE and WNW-ESE directions. The trend of the foliation, defined by parallel orientation of mafic minerals, is more or less the same throughout and is generally along the NNE-SSW direction swinging frequently to N-S with easterly dips ranging from 30° to 40°.

Petrography

The medium-grained rocks of the area exhibit distinct gneissic banding consisting of alternating bands of leucocratic and melanocratic minerals of quartz, plagioclase and subordinate amounts of potash feldspars in the former and hornblende and biotite in the latter respectively. Based on mineralogy (Table 1), three types could be recognized using IUGS systematics after Streckeisen⁸, namely: (i) tonalite, (ii) granodiorite and (iii) granite (Figure 2). The granitoids fall in the IAG + CAG fields after Maniar and Piccoli⁹. In thin sections, the feldspars are mostly plagioclase (An_{14-32}) with minor amounts of

orthoclase and microcline, the latter minerals are seen more in granite (s.s.). The plagioclase grains are both twinned, generally, on albite-albite law and untwinned. Sericitization of feldspars is noticed in some sections. The orthoclase is occasionally perthitic and microcline is interstitial between quartz and plagioclase grains. Myrmekitic intergrowths are rarely noticed. The mafic minerals include prevalent hornblende ($2V_x = 68-78^\circ$; $Z^c = 17-19^\circ$), followed by biotite which is distinctly pleochroic from brown to greenish brown. The common minor accessories are sphene, apatite and magnetite.

Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0

Sample Nos. 1 to 3 = Tonalite; 4 to 6 = Granodiorite; 7 = Granite.

Petrochemistry

Seven representative samples were carefully selected for chemical analyses. Major elements were determined by conventional wet methods and trace elements were determined by atomic absorption spectrophotometer. Rare earth elements (REE) on selected samples were determined by using spark source mass spectrometry¹⁰. The precision ($\pm 5\%$) and accuracy were checked by using standards and by performing duplicate analyses. The chemical data of the granitic rocks of Krishnagiri are given in Table 2. Table 3 presents some diagnostic chemical parameters.

Major elements

From Table 2, it is observed that from tonalite to granite, there is a gradual increase of SiO_2 , K_2O and gradual decrease of MgO , CaO , Na_2O and Sr , while the remaining oxides show fluctuations. In the differentiation index (DI) diagram (Figure 3), with increasing DI, there is an increase in SiO_2 , K_2O , Ba , K/Rb , K/Ba and K/Sr and decrease in Na_2O , MgO , CaO and Sr . All the parameters trace a smooth trend against DI, suggesting that these granitoids are cogenetic. In case of the Ca-Na-K distribution, the granitoids follow a calcalkaline trend¹¹. $\text{Na}_2\text{O}/\text{K}_2\text{O}$, which usually will be less than one in the microcline rich granites, is high and more than one (average 2.18) and seems to be controlled by the abundance of plagioclase in the rocks testifying to their dominant tonalite-granodiorite composition¹². World-wide observations indicate that soda-rich granitoids are of Archaean age and K-rich granitoids are of Proterozoic

Figure 2. Modal Q-A-P plot using IUGS systematics after Streckeisen⁸. Description of the samples are as given in Table 1. IAG = Island Arc Granites; CAG = Continental Arc Granites; CCG = Continental Collision Granites. The fields are after Maniar and Piccoli⁹.

RESEARCH ARTICLES

and younger age¹³. The tonalite–granodiorite suites of the Shimoga–Honali, Holenarsipur and Chitradurga, having Na₂O/K₂O ratio more than one, have yielded an age older¹⁴ than 2.5 b.y, whereas granitoids of adamellite–granite compositions from Closepet area, with the ratio less than one, are younger¹⁵ than 2.5 b.y.

The granitoids of the area are dominantly metaluminous with A/CNK values being less than unity except for one sample which is slightly peraluminous (average A/CNK and A/NK are 0.95 and 1.68 respectively). The agpaitic index is less than one indicating subsolvus nature of these granitoids. Barker *et al.*¹⁶ and Barker¹⁷

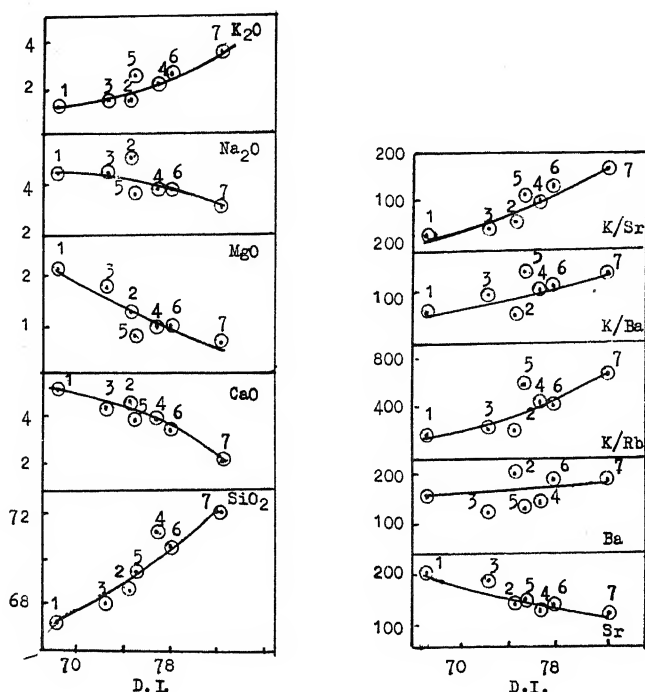

Figure 3. Plots of the major and trace elements against differentiation index (DI), for the granitic rocks of Krishnagiri. Symbols as in Figure 2.

have classified the granitic rocks into high alumina and low alumina types using weight percentages of SiO_2 and Al_2O_3 . Barker¹⁷ has indicated 15% Al_2O_3 at 70% SiO_2 as the dividing point for these two types. Recently, Sarvothaman¹⁸ has suggested, after an elaborate study, that the specifically calculated $\text{SiO}_2/\text{Al}_2\text{O}_3$ ratio depicts an unequivocal demarcation between low- and high-alumina types. The $\text{SiO}_2/\text{Al}_2\text{O}_3$ ratio for the granitic rocks of Krishnagiri ranges from 4.24 to 4.99, thereby assigning them to moderate to high-alumina type.

Trace elements

Barium. Ba shows generally moderate values varying from 135 to 215 ppm averaging 174 ppm. The K/Ba ratio, depicting wide fluctuations from 57 to 150 and averaging 106, shows an increase with increase in DI (Figure 3). Ba/Sr ratios of these granitoids are low to moderate with the average value of 0.81. Similar value is reported for Marginal Gneiss Suite (average 0.97) of Holenarsipur Belt of Karnataka¹⁹.

Rubidium. Rb values in the present granitic rocks show scatter very narrowly from 35 to 57 ppm and correlating with the low potash content of the rocks. The average value of 45 ppm in this suite is fairly comparable to the Kaptipada tonalite–granodiorite suite of Singhbhum Craton (average 60 ppm)⁷ and mean Archaean High alumina tonalite (average 44)²⁰. The K/Rb values

show wide variations from 222 to 700 with the average value of 420.

Strontium. Sr levels in the present case depict appreciable fluctuations (from 172 to 312 ppm) showing depletion towards higher SiO_2 levels and sympathetic with behaviour of Ca. The values are (average 228 ppm) correlating well with the Ca content (average 2.80) of this suite. The average Rb/Sr ratio of 0.21 is closely comparable to those of Phases I and II of Singhbhum granitoid with tonalite–granodiorite composition (average 0.21)²¹, of tonalite–granodiorite suite of Kaptipada (average 0.19)⁷ and of equigranular granitoid suite of the Bonai Pluton (average 0.21)²².

Nickel. Ni content of this suite ranges from 17 to 31 ppm with an average value of 24 ppm, which is fairly similar to the concentrations reported for the trondhjemites of Hassan District (average 19 ppm)²³ and for tonalites of Dharwar Craton (average 16.5 ± 4.9 ppm)²⁴.

Chromium. Cr values, varying from 17 to 30 ppm, show decrease towards increase in SiO_2 .

Yttrium. The granitic rocks of the area show lower values of Y ranging from 12 to 22 ppm averaging 16 ppm. Y_N depicts negative correlation with Ce_N/Y_N , which probably suggests the role of garnet in the formation of granitic precursors²⁵. A positive correlation is seen between Y and TiO_2 (Figure 4).

Zirconium. The concentration of Zr shows limited range of variations from 131 ppm to 181 ppm averaging 158 ppm, which is moderately low like other Archaean gneisses²⁰. Similar to Y, Zr also exhibits a linear correlation with TiO_2 (Figure 4).

Rare earth elements. The granitic rocks show narrow ranges in REE abundances (66.63–80.65 ppm). Ce_N/Yb_N ratio ranges from 9.64–16.78 averaging 12.59. La_N/Yb_N ratio exhibits very high values ranging from 28.47 to 59.16, whereas, La_N/Sm_N values show a limited range of variation (3.33–4.23).

The chondrite normalized REE patterns in these granitoids show a highly fractionated nature with a conspicuous LREE enrichment and HREE depletion (Figure 5). Generally, they show slight to moderate negative Eu anomaly with Eu/Eu^* ratio ranging from 0.50 to 0.82.

Discussion and conclusion

The calc-alkaline affinity of the grey granitic rocks of the area suggests their emplacement under thick continental crustal conditions indicating greater temperatures in the lower crust, a situation capable of generating

Figure 4. TiO_2 versus Y and Zr diagram. The samples show a linear correlation between the elements. Symbols as in Figure 2.

Figure 5. Chondrite normalized REE abundances of granitoids of Krishnagiri. Description of the samples as in Figure 2. A = sample no. KP-5 of Kaptipada⁷.

large volumes of tonalitic magmas. The phenomenon appears characteristic of early stages of many magmatic cycles recorded in shields^{17,26-28}. Many workers^{11,20,28} advocated different models for the origin of calc-alkaline orthogneisses. They are:

- the nature of source rocks – various mantle compositions, gabbros, wet basalts, amphibolites, simatic and sialic granulitic crust, greywackes, other sediments, etc.
- the process – partial melting and fractional crystallization of variable nature and degree involving garnet, amphibole and/or plagioclase as residual or fractionating phases.

The general high content of certain oxides like TiO_2 , MgO and trace elements such as Sr and Ni in these granitoids suggests the presence of mafic components in the source region²⁹. The higher values of these elements reflect the characteristics of a magma evolving probably from an amphibolite-bearing source. A similar source has been invoked for the granitic rocks of India^{7,23,30}. The amphibolite enclaves are considered to be relics of a basaltic crust and suggest as a source for the tonalite–granodiorite suite of Nuk Gneiss³¹. Amphibolite, occurring as enclaves, has been regarded as the source for the various tonalite–granodiorite suites of India^{7,22,23}.

The highly fractionated REE patterns with high LREE/HREE ratios suggest the role of hornblende/garnet in the source rocks of Krishnagiri granitoids^{32,33}. The moderate to high Ce_N/Y_N ratios (4.34–8.19) imply that Y is retained in residual garnet³⁴. Positive correlation of Y and Zr with TiO_2 , negative correlation between Y_N and Ce_N/Y_N and high LREE/HREE ratio are in conformity with equilibration between melt and solid that is controlled generally by garnet³⁵⁻³⁷. Also granitoids which are considered to have residual garnet in their partial melt have Ce_N/Yb_N ratio³⁸⁻⁴⁰ more than 10. This ratio in the granitoids of the area ranges from 9.64 to 16.78, supporting the presence of garnet in the residual melt.

Possible mechanisms have been explored, regarding the process of formation of the granitic rocks of Krishnagiri. The subordinate occurrence of granite (s.s.) in the present area precludes the formation by ensialic anatexis. The absence of petrographic features like albitization of plagioclase and replacement of plagioclase by potash feldspar rule out the process of metasomatism as well. Also the model of fractional crystallization is set aside as there is distinct absence of intermediate rocks, like syenites and/or diorites and also there is no continuous order of basic to acidic rocks except for quartz-rich granites (s.l.). The most appropriate mechanism appears to be partial melting of basic rocks. It has been envisaged that the formation of cumulates during the fractional crystallization of a basic magma of mantle derivation emplaced into the lower crust in a tensional tectonic environment liberates hidden heat which brings about partial melting in the lower crust^{16,41}. Ellis and Thompson⁴², after conducting partial melting experiments, have observed that a suite of calc-alkaline rocks can originate by melting of amphibolites or basalt (or similar basic rocks) and that during the partial melting of basic rocks, say at 1000°C and one atmosphere pressure, the melts produce metaluminous granites and are, therefore, diopside normative, whereas at 5 kb pressure range, basic rocks may give rise to melts of metaluminous granites at temperatures far below 1000°C . The granitic rocks of the area are dominantly metalu-

minous with the average ASI value less than unity. In view of the above contention, the process of partial melting of amphibolite source appears to be more tenable in the evolution of the granitic suite in this area. The same process has been attributed to the origin of similar granitic rocks in several parts of Peninsular India^{7,23,33}.

Several occurrences of I- and S-type granites are reported in the Indian shield by Dhanaraju *et al.*¹³. Most of the following features indicate I-type characteristics^{13,43,44} for the granitoids in this region: (i) high Na₂O content, (ii) average molar A/CNK ratio is 0.95, indicating metaluminous nature, (iii) average molar A/NK ratio is 1.67, (iv) dominant diopside normative, (v) regular inter-elemental behaviour, (vi) biotite and hornblende as mafic minerals, (vii) ubiquitous amphibolite enclaves and (viii) presence of sphene and apatite as common accessories.

Geochemical signatures in granitic rocks are controlled by their source characteristics⁴⁵. These granitoids might have inherited the petrochemical features probably from an 'enriched' mantle or lower crust, with mafic constituents^{29,30}. The above assumption is supported by the high abundances of certain elements in these granitoids as mentioned earlier and I-type lineages with lower Rb/Sr ratio. The I-type granitoids are genetically related to the mantle source⁴³. Similar source characteristics have been invoked for the tonalite–granodiorite suite of the Kaptipada area having the same petrological features⁷ as that of the granitoids of the present area (Table 4).

Maniar and Piccoli⁹ have devised a number of discriminant diagrams using major element chemistry in order to know the geotectonic environment in which granitic rocks are emplaced. In the diagram employing A/NK versus A/CNK ratios, a clear demarcation of Island Arc Granites (IAG), Continental Arc Granites (CAG) and Continental Collision Granites (CCG) could be made effectively. In the binary diagram employing the above ratios (Figure 6), the granitic rocks of the Krishnagiri area plot themselves in IAG + CAG field, which has already been attested in the modal diagram (Figure 2). The IAG + CAG granites have A/CNK values less than 1.15, which is highlighted in the present granitic rocks. The authors⁹ further rule out the possibility of discriminating between IAG and CAG based on the major elements.

Possibility of proton oscillations through the benzene ring

R. S. Shresth, R. Manickavasagam, S. Mahapatra and N. Sathyamurthy*

Department of Chemistry, Indian Institute of Technology, Kanpur 208 016, India

The possibility of proton oscillations above and below the plane of the benzene ring, through its centroid, in protonated benzene is pointed out, in this communication.

PROTONATION of benzene and other aromatic hydrocarbons has been studied over the years by a variety of methods¹. The nature of the arenium ion that is formed as the transition state in an electrophilic aromatic substitution has been the focus of attention of a number of experimental and theoretical studies (for example, see ref. 2 and references therein). It is generally believed that a π -complex (1) is formed first and then it rearranges into a σ -complex (2) before it results in products.

When $X=Y=H$, there is an interesting possibility: the proton in (1) could lie either above or below the plane of the benzene ring and it could undergo an oscillatory motion between the two positions, through the centre of the ring.

In order to examine such a possibility we have computed the $H^+-C_6H_6$ interaction energy keeping C_6H_6 in its equilibrium geometry³ ($r_{C-C}=1.386$ Å, $r_{C-H}=1.076$ Å) and varying the distance (Z) of H^+ from the centre of the C_6H_6 plane by the LCAO-MO-SCF approach using the 6-311G basis set and the Gaussian 94 set of programs⁴.

It is clear from the results shown in Figure 1 that there is a potential well of depth of 4.38 eV, with the minimum at $Z=\pm 1.1$ Å and that we are dealing with a stable ionic species that is likely to be found in nature. Mulliken population analysis reveals that there is substantial charge transfer between C_6H_6 and H^+ at such short distances.

Geometry optimization calculations reveal that even when the proton is at the centre of the ring, the ring is only slightly enlarged ($r_{C-C}=1.424$ Å; $r_{C-H}=1.068$ Å) and that the energy difference between the distorted and the undistorted geometries is only 0.23 eV, implying that the proton can go through the centre of ring. It is worth emphasizing that the energy of the $C_6H_7^+$ ion with

an H in the geometric centre of the benzene ring is well below (-1.8 eV) that for the separated $C_6H_6 + H^+$ and that there are several bound states corresponding to the oscillatory motion above and below the plane of the ring as can be seen from Figure 1. These bound states were computed using the Fourier grid Hamiltonian approach⁵. A close examination of the figure suggests three types of oscillations. For $0 \leq V \leq -1.8$ eV, there would be 'free' oscillation of the proton between the two sides of the ring. For energies just below the barrier (-1.8 eV), there is the possibility of tunneling. For energies well below the barrier, the proton would oscillate about the equilibrium position on either side.

In order to make sure that our findings are not dependent on the quality of the basis set, we have computed the entire potential-energy curve shown in Figure 1 using 6-311G** basis set, which includes polarization functions. While the depth of the well and the height of the barrier in between change in magnitude with the basis set, the major features of the double well potential remain the same.

It is worth pointing out that several semiempirical and *ab initio* calculations (for example, see ref. 6) on $C_6H_7^+$ have shown that the σ complex (2) is more stable than the π complex (1), in the context of electrophilic aromatic substitution. But that is not quite relevant to the present investigation which focuses attention on the penetration of the ring by a proton.

The possibility of the charge transfer ($C_6H_6 + H$) channel suggests that the proton undergoing oscillatory motion between the two sides of the benzene ring may not stay attached to the ring forever. The lifetime of the species would depend on the crossing (or avoided crossing) between the potential energy curves for $C_6H_6 - H^+$ and $C_6H_6^+ - H$ interaction. Investigation of this aspect of the problem is presently being taken up. Regardless of the nature of the crossing between the two curves, the

Figure 1. The interaction potential for $H^+-C_6H_6$ with the zero of energy corresponding to the asymptotically separated H^+ and C_6H_6 in its equilibrium geometry. For reference, the energy of $C_6H_6^+ + H$ state is included in the figure.

*Honorary Professor, S. N. Bose National Centre for Basic Sciences, Calcutta, India.

proposed structure can be expected to play an important role in proton-benzene collisions⁷. Also, under conditions as in a mass spectrometer or in interstellar clouds⁸ $C_6H_7^+$ could live for a sufficiently long time and transitions between its electronic states and also between the bound states supported by the double well potential could account for some of the hitherto unaccounted emissions, particularly in the long wavelength regions.

Preliminary calculations⁹ show that there are no significant minima but there exist barriers to penetration through the ring in the interaction of C_6H_6 with H, H⁺ and He, thus making H⁺ a unique partner in exhibiting such an oscillatory motion.

If such a motion could exist in protonated benzene, it could exist in a variety of other protonated aromatic hydrocarbons such as naphthalene, anthracene, etc. We have indeed found this to be the case⁹.

There has been a lot of interest in collisions of neutrals and charged species with fullerenes and the possibility of trapping atoms/ions inside the cage¹⁰. In this context the possibility of proton motion through the ring becomes quite relevant.

Nucleotide frequency map: A new technique for pictorial representation of dinucleotide frequencies

Archana Pan, Soumalee Basu, Chitra Dutta, Debi Prasad Burma* and Ranjana Mukherjee*

Theoretical Biology Group, Biophysics Division, Indian Institute of Chemical Biology, Calcutta 700 032, India

*Molecular Biology Unit, Institute of Medical Sciences, Banaras Hindu University, Varanasi 221 005, India

In this communication, a method of presentation of dinucleotide frequencies in the form of a contour diagram (map), designated as dinucleotide frequency map (DNFM), has been used for the first time to analyse the compositional bias of different nucleic acid sequences. Such maps provide a method of visualization of the nucleotide usage at a glance and allow simultaneous representation and comparative analysis of multiple sequences of different origins. Using the technique of DNFM, it has been shown that the dinucleotide frequency distribution profile of any nucleotide sequence often exhibits distinct statistical bias, which is not predictable from the knowledge of its base composition. Analysis of bacterial rDNA operons showed that 16S and 23S rRNA genes of such species, in general, follow similar dinucleotide patterns, which are different from those of the intervening regions. The technique of DNFM has also been applied to analyse the compositional heterogeneity of the genomic sequence of the bacteriophage lambda to show that the dinucleotide frequencies vary along the phage genome depending on the distribution of open reading frames.

COMPOSITIONAL heterogeneity is an intrinsic feature of natural nucleic acid sequences. At the genome level, eukaryotic and prokaryotic sequences exhibit hierarchy in the frequencies of appearance of most dinucleotides¹. Instances of distinct bias in dinucleotide usage in genomic sequences include underrepresentation of T_pA and overrepresentation of G_pC in most temperate bacteriophage sequences², C_pG suppression in vertebrate non-oncogenes^{3,4}, animal mitochondrial genomes and many thermophilic bacterial sequences² and abundance of G_pG/C_pC in animal mitochondrial genomes and chloroplast genomes⁵. A revealing contrast in statistical composition is often observed for long versus short DNA sequences, primarily because of the presence of local signals² such as promoter, enhancer and termination signals, or genetic mosaicism resulting from horizontal gene transfer, transposition or recombination events and also due to the fact that coding and non-coding regions of any sequence, in general, have distinct bias in short oligonucleotide distributions^{6,7}. Interpretation to such compositional heterogeneity usually centres on structural or conformational preferences², context-dependent mutational events^{8,9}, methylation effects^{2,10} processes of rep-

lication and repair^{8,9}, etc. Nucleosome positioning interactions with DNA-binding proteins and ribosomal binding of mRNA are known to be strongly affected by dinucleotide arrangements^{11,12}. It has recently been suggested² that conformational stacking arrangements are principally determined by dinucleotide configurations. Replication error rates, including nucleotide misincorporation and transient misalignment, have also been shown to be context-dependent^{8,9}.

Realizing the importance of compositional analysis of nucleic acid sequences, a series of analytical computational and graphical techniques have been developed^{1-5,7,13-15}. However, a major problem of nucleotide usage analysis is the involvement of a large number of variables. Even a simple comparative analysis of the dinucleotide usage in different DNA/RNA sequences involves handling of two or more sets (for pairwise comparison or simultaneous comparison of multiple sequences), each having 16 different numbers. For trinucleotide frequency analysis, the number is four times higher. Both the qualitative and quantitative analyses of such a large number of variables would practically be impossible unless a suitable method for visual representation of these numbers is developed. It is in this context that the present report describes a technique used for the first time for pictorial representation of the dinucleotide frequencies of any nucleic acid sequence using contour maps, which will enable quick visual comparative assessment of the data at a glance. These maps, designated as dinucleotide frequency maps (DNFMs), have been used to analyse the compositional bias of different sequences.

The basic formalism for construction of DNFMs is as follows: The percentage of occurrence of sixteen dinucleotides in the query sequence has been plotted along the lines joining the centre of the regular sixteen-sided polygon and its vertices, where each vertex corresponds to a particular dinucleotide and appropriate maximum and minimum values of the dinucleotide frequencies are assigned to the vertices and the centre respectively. All the consecutive points plotted along different axes are joined to get the DNFM of the sequence. More than one sequence can be mapped on the DNFM following the same formalism.

It is worth mentioning at this point that sixteen dinucleotides can be arranged in $(15!)/2$ different ways

(! means factorial). By several trials it has been found that the order of presentation as per the first two bases in the codons, as they appear in the tabular form of the genetic code, provides an attractive visual impact, even for most of the non-coding sequences (such as rDNA sequences) so far examined by our group.

The technique has been applied to analyse the compositional bias that might exist in different nucleotide sequences, both at the gene and genome levels. The question often raised in dinucleotide usage studies is whether the di-, tri- and higher-order nucleotide distributions of any sequence are merely the consequences of its base composition or do they truly reflect preferences for certain sequence patterns. To address this issue, sequences of small subunit rRNA genes of tomato, strawberry, *Leishmania donovani* and *Leishmania major* having similar base compositions (Table 1) were taken from the database and a random sequence having the average length and base composition of these sequences (Table 1) was generated through first-order Markov Chain simulation. The latter sequence was taken as a control, as it should have the dinucleotide compositions expected from its mononucleotide frequencies. Figure 1 shows the DNFMs of these rDNA sequences along with the control sequence. While the rDNA sequences from the plants (red and yellow) exhibited similar DNFMs, those from the parasites (blue and pink) produced a visibly different map. None of the DNFMs follows the trajectory exhibited by the random sequence (green) having similar base composition. In all the four rDNA sequences examined, the percentage of occurrence of the dinucleotides G_pC , G_pT , A_pG and T_pA was significantly lower and that of the dinucleotides T_pT , G_pG and A_pA was higher than that expected from their mononucleotide composition. In the plant sequences, A_pT was overrepresented, while the parasite sequences exhibited an abundance in C_pA . There were many such instances which suggest that the dinucleotide distribution in a sequence is not a consequence of its base composition.

To examine the extent of compositional homogeneity in small segments (say, an operon) of the genome(s) of a species, the DNFMs of different segments of the rDNA operons of different bacterial species have been generated. The DNFMs of 16S and 23S rRNA genes of *E. coli* and their intervening spacer region are shown in Figure 2. In most of the cases examined so far, the

RESEARCH COMMUNICATIONS

DNFMs of 16S and 23S rRNA genes follow almost similar contours, while that of the spacer region (usually including a couple of tRNA genes) exhibits a distinct trajectory (Figure 2). Thus, the small and large subunit rRNA genes, though generally do not have significant sequence homology, follow similar dinucleotide distribution patterns, which are distinctly different from those of the intervening regions.

The technique of DNFM may also be applied to analyse the global distribution of dinucleotides in genomic sequences. The circular genomic sequence of lambda, a linearized version of which is available at the GenBank, has a striking feature concerning the distribution of the coding regions along its two strands. For the first 20,000 and last 8,000 bases (approx.) of the genome (total length 48,502 bases), all the known and putative open reading frames (ORFs) are found to occur in the reported strand, while all ORFs in the region starting from 20,147 to 37,940 bases are in the complementary strand. To examine whether dinucleotide distribution pattern is similar throughout the genome, or it differs between coding and non-coding region, the genomic sequence was divided into different parts and the DNFM of each segment was generated (Figure 3). The DNFMs of the two parts from the first 20,000 bases of the genome (representing the coding strand) follow similar contours except small deviations along a few axes (pink and blue), but those from the middle portion of the genome (representing sequences complementary to the coding region), though resembling one another (green and red), are quite distinct from those

of the coding strand. Both the sequences from the coding part of the genome exhibit abundance in G_pC , G_pA , G_pG and C_pG , while the dinucleotides T_pT , T_pC , T_pA and A_pT are overrepresented in the non-coding region of the genome. Similar results were obtained when the sequence was divided into segments having smaller lengths. This indicates that the dinucleotide usage patterns vary along the genome of lambda depending on the distribution of ORFs. However, when the DNFM of the complementary sequence of the middle portion (20,147

Figure 2. Comparison of 16S, 23S rRNA genes and their intervening spacer region of *E. coli* (V00348). Pink: 16S rRNA gene; green: 23S rRNA gene; blue: intervening spacer region. The centre and each vertex represent respectively 0 and 10% occurrence of the dinucleotides.

Yellow: *L. esculentum* (tomato) ($\times 13828$) 1800 bases; red: *F. ananassa* (strawberry) ($\times 15590$) 1804 bases; blue: *L. donovani* ($\times 07773$) 2205 bases; pink: *L. major* ($\times 53915$) 2137 bases; green: random sequence having average base composition of the above four sequences as mentioned in Table 1, 2000 bases. The centre and each vertex represent respectively 3 and 8.5% occurrence of the dinucleotides.

Figure 3. Dinucleotide frequency maps of different parts of sequences of Lambda genome (V00636). Pink: bases 1-10000; blue: bases 10001-20000; green: bases 20151-29151; red: bases 29152-37652. The centre and each vertex represent respectively 0 and 10% occurrence of the dinucleotides.

to 37,940) of the genome, which represents the actual coding sequence, was generated the pattern did not show similarity to those of the coding sequences in the first 20,000 bases of the genome (data not shown). Thus all the coding regions of the genome do not exhibit similar compositional bias.

The compositional heterogeneities of nucleotide sequences at isochore level were analysed by Karlin *et al.*² using dinucleotide relative abundance values, which assess the contrast between observed dinucleotide frequencies and those expected from the component mononucleotide frequencies. A differential map plotting such dinucleotide relative abundance values can be constructed following a formalism similar to that reported here. However, such differential maps will be statistically significant only for long contigs of DNA sequences (> 100 kb) and hence will not be suitable to analyse the local bias in sequences. This formalism may be extrapolated to map the trinucleotide frequencies of any sequence, in which the map will have sixty-four axes instead of sixteen.

It has already been reported that compositional analysis of nucleotide sequences can be used to address various problems such as discrimination between introns and exons of eukaryotic sequences⁷, presence of local bias in dinucleotide compositions in regulatory regions of the genome (promoter, enhancer, etc.)², assessment of the coding potential of putative ORFs in uncharacterized DNA sequences, etc.⁶. However, all these studies involve a large number of numerical variables and the technique described here might be useful for simultaneous pictorial representation and visual comparison of such variables. Some of these problems are currently under study in our laboratory.

Differences in energy metabolism in cells of neuronal and glial origin – ³¹P NMR spectroscopic study

Archana Singh and Nanda B. Joshi

Department of Biophysics, National Institute of Mental Health and Neurosciences, Bangalore 560 029, India

³¹P NMR spectroscopy has been used to study the energy metabolism in PC12 and U-87MG cells of neuronal and glial origin respectively. Both types of cells exhibited the resonances arising from adenosine triphosphate, inorganic phosphate and phosphomonoester. In addition, phosphocreatine was found to be present in PC12 cells whereas in U-87MG cells a prominent resonance due to diphosphodiester was observed. The pathways of ATP production were investigated using specific inhibitors of glycolysis and oxidative phosphorylation. Both glycolysis and oxidative phosphorylation pathways contribute to ATP production in PC12 cells, whereas oxidative phosphorylation was found to be the major ATP producing pathway in U-87MG cells. These results indicate that the energy-producing pathways in the cells of neuronal and glial origin could be different.

ADENOSINE TRIPHOSPHATE (ATP) serves as a primary currency of cells, fuelling cellular processes from macromolecular synthesis to signal transduction. It is well known that ATP production is tightly coupled to its consumption. The viability of cells depends on their energy utilization and it is probable that cell death, which is related to a breakdown in membrane function and/or inhibition in macromolecular synthesis, is produced by a local decrease of ATP below a critical level. This suggests that a large and unfavourable perturbation in the energy pathways could be responsible for an impaired cellular function. An impairment in the energy metabolic pathways of the affected cells or tissues has been observed in many neuronal disorders¹⁻⁶. Very often, changes in the normal functioning of cells have been shown to be affected due to the alterations in the energy utilization pathways⁷⁻¹¹. A detailed understanding of cel-

lular energy metabolism is, therefore, vital. NMR spectroscopy is ideally suited for investigating the cellular energy metabolism of intact cells¹²⁻¹⁶. ³¹P NMR spectroscopy of cells provides quantitative information about the various phosphorylated metabolites produced in the energy production and utilization pathways. In addition, intracellular pH and phospholipid metabolism can be studied using ³¹P NMR spectroscopy. In the present study, the energy metabolism in cells of neuronal (PC12) and glial (U-87MG) origin has been investigated using ³¹P NMR spectroscopy.

Eagle's minimum essential medium (EMEM) and RPMI-1640 were purchased from Hi-media, Bombay (India). Foetal calf serum was obtained from Biological Industries, Israel. Bovine and horse serum were prepared in the laboratory. Sodium pyruvate, glutamine, glucose, N-2-hydroxy methyl piperazine-N-2 ethane sulfonic acid (HEPES), deuterium oxide (D₂O) and 2-deoxy-D-glucose (2-DG) were purchased from Sigma (USA) while sodium azide was obtained from Loba Chemie Indo Astranal Co., Bombay (India). All other chemicals were procured from various commercial sources and were of analytical grade.

PC12, a rat pheochromocytoma cell line, was obtained from National Tissue Culture Facility (NTCF), Pune (India) and U-87MG, a glioblastoma-astrocytoma cell line, was procured from American Type Culture Collection (ATCC), Rockville, MD (USA). Cells were grown in Nunc plastic tissue culture flasks or in glass bottles at 37°C under CO₂ environment. For PC12 cells, the growth medium consisted of RPMI-1640 with 10% horse serum, 5% foetal calf serum, 20 mM Hepes, 2 mM glutamine, 10 mM sodium bicarbonate and antibiotics. The growth medium for U-87MG cells consisted of EMEM with 5% foetal calf serum, 5% bovine serum, 10 mM Hepes, 1 mM sodium pyruvate and antibiotics. The cells were harvested at 120 h, centrifuged at 1500 rpm for 10 min and resuspended in HBSS containing glucose.

Cells were embedded in an agarose gel matrix in the form of threads so that the cells were held stationary in the NMR tube. Cell embedded gel threads were prepared by the method of Lyon *et al.*¹⁷. Briefly a solution of low gelling temperature agarose (2.6% w/v) was prepared in Hank's balanced salts solution (HBSS) at 50°C. Subsequently, the agarose solution was cooled to 37°C and 1 ml of this solution was mixed with 1 ml of cell suspension so that a typical sample contained 200 × 10⁶ cells/ml. The gel matrix was then extruded under mild pressure through a coil of teflon tubing (0.5 mm i.d.) chilled in an ice-water bath at 10°C. The cell embedded gel threads were collected directly into 1 ml HBSS at the bottom of a 10 mm NMR tube. The 10 mm Wilmad screw cap NMR tube was modified to allow the perfusion of cells. A perfusion insert was fabricated with an inlet and outlet tubing. The insert was fixed on top of the NMR tube after the gel threads

were collected. The cells embedded in the gel threads were perfused with balanced salt solution using a peristaltic pump with a flow rate of 1 ml/min.

³¹P NMR measurements were performed on a Bruker AMX-400 NMR spectrometer with wide bore using 10 mm broad band probe. Spectra were acquired with a field frequency D₂O lock and without proton decoupling. Magnetic field homogeneity was adjusted by maximizing the D₂O free induction decay. ³¹P NMR spectra were obtained at 161.98 MHz using a 15 μs excitation pulse and 1 sec delay time. Chemical shift was measured relative to phosphoric acid and the measurements were performed at 22°C. ³¹P NMR experiments have been performed 3-5 times for both PC12 and U-87MG cells from different passages. The results were reproducible, however, the ³¹P NMR spectra shown in Figure 1 are from typical experiments.

Cell viability was measured using trypan blue dye exclusion method after embedding the cells in the agarose gel threads and again after the NMR experiments were completed. 90-95% cells were found viable at the end of the NMR experiments. This clearly indicates that the cells were metabolically active during the NMR measurements.

Figure 1 shows the ³¹P NMR spectra of PC12 and U-87MG cells from typical experiments. Both PC12 and U-87MG cells showed resonances arising from ATP, P_i and phosphomonoesters (PME). PC12 cells also showed a resonance due to phosphocreatine (PCr) which was absent in U-87MG cells. On the other hand, U-87MG cells showed a pronounced resonance due to diphosphodiester (DPDE), which was relatively small in PC12 cells. Since PCr is produced by the enzymatic reaction involving creatine kinase (CK), it is probable that the

Figure 1. ³¹P NMR spectra of PC12 and U-87MG cells embedded in agarose gel threads and perfused with HBSS containing glucose during the NMR experiments. *a*, PC12 cells and, *b*, U-87MG cells. Spectra were collected 1 h after casting the gel threads. Peaks are assigned as: (1) PME; (2) P_i; (3) PCr; (4) γ-ATP; (5) α-ATP; (6) DPDE and (7) β-ATP.

absence of PCr signal in ^{31}P NMR spectrum of U-87MG cells could be due to the impaired CK activity in these cells. It is also possible that PCr may be present in U-87MG cells in the bound form and therefore is inaccessible to the detection by NMR technique. Holtzmann *et al.*¹⁸ have proposed that in the brain PCr is present in at least two different compartments, one is labile and thought to be present in neuronal cells and the other is stable and is present in astrocytes. The DPDE resonance observed in ^{31}P NMR spectra may arise from the uridine-diphosphosugars, in particular from uridine diphosphoglucose (UDPG). When glucose enters the cells, it may be metabolized to yield energy or it may be stored as an energy reserve in the form of glycogen. The synthesis of glycogen involves the formation of UDPG. The DPDE peak observed in ^{31}P NMR spectrum of U-87MG cells indicates the presence of glycogen reserves in these cells. Glycogen granules are known to be characteristic of astrocytes¹⁹. The PME peak, which was observed in both the cell types, may arise from phosphoethanolamine, phosphocholine and sugar phosphates in the cells¹⁵.

The peak positions of ATP and P_i were almost the same in both types of cells. The same position of P_i (1.9 ppm) in both types of cells suggests that the intracellular pH of these cells is almost similar. The intracellular pH was calculated using the equation¹¹.

$$\text{pH}_i = 6.66 + \log(\text{P}_i - 3.079)/(5.57 - \text{P}_i),$$

where P_i is the chemical shift of the inorganic phosphate peak relative to PCr peak. The pH_i of PC12 cells, thus calculated, was found to be 7.38. We could not calculate the pH_i in case of U-87MG cells as the PCr peak was not observed in these cells.

To determine the pathways of ATP production, the cells were perfused with the medium containing sodium azide and 2-deoxy-D-glucose (2-DG) during the NMR measurements. Sodium azide is an inhibitor of oxidative phosphorylation and prevents the production of ATP by blocking cytochrome oxidase, the last step in the electron transport chain. On the other hand, 2-DG blocks the glucose metabolism and inhibits the ATP production by glycolysis. On perfusing PC12 cells with the medium containing sodium azide, the PCr peak disappeared and a partial decrease in ATP was observed. However, on perfusing U-87MG cells with the medium containing sodium azide, a significant inhibition in ATP peaks was observed. Perfusion of PC12 cells with the medium containing 2-DG caused the appearance of 2-deoxy-D-glucose-6-phosphate (2-DG6P) with a complete inhibition of ATP peaks. U-87MG cells showed a small decrease in ATP signal on perfusing with the medium containing 2-DG, and an additional peak due to 2-DG6P was observed. These results are shown in Table 1 in

Table 1. The ratio of inorganic phosphate (P_i) and adenosine triphosphate ($\beta\text{-ATP}$) in PC12 and U-87MG cells perfused with HBSS

Perfusion medium	$\text{P}_i/\beta\text{-ATP}$	
	PC12 cells	U-87MG cells
HBSS + glucose	0.80 ± 0.15	0.33 ± 0.09
HBSS + glucose + NaN_3	0.97 ± 0.30	4.10 ± 0.54
HBSS + glucose + NaN_3 + 2DG	21.80 ± 1.83	4.27 ± 0.53

Cells were embedded in agarose gel threads and were perfused with HBSS during the NMR measurements. NaN_3 or NaN_3 + 2DG were added to the perfusate one hour before starting the experiments and were present during the data collection. $\text{P}_i/\beta\text{-ATP}$ ratio given is the mean \pm SE of three experiments.

terms of the ratio of P_i and $\beta\text{-ATP}$ ($\text{P}_i/\beta\text{-ATP}$). In presence of NaN_3 in the perfusion medium, no appreciable change in the ratio of $\text{P}_i/\beta\text{-ATP}$ was observed in PC12 cells while U-87MG cells showed an increase in $\text{P}_i/\beta\text{-ATP}$ ratio. On addition of 2-DG to the perfusion medium the $\text{P}_i/\beta\text{-ATP}$ ratio showed no change in U-87MG cells, however, in PC12 cells an increase in the same was observed. In PC12 cells, the inability of sodium azide to inhibit the ATP peaks indicates that glycolysis also contributes to ATP generation. This is further confirmed by inhibition of ATP peaks in the presence of 2-DG. Thus in PC12 cells, ATP is generated by both glycolysis and oxidative phosphorylation. On the other hand, in U-87MG cells, a significant inhibition of ATP by sodium azide and no further inhibition by 2-DG suggest that oxidative phosphorylation is the major pathway of ATP production.

The present study has shown that the cells of neuronal and glial origin have some differences in their energy metabolic pathways. These cells appear to differ in their energy metabolism and the differences in the cellular energy metabolism may probably be due to their specialized functional role.

Anomalous helium emission: Precursor to earthquakes

Debasis Ghose, Nishith Kr. Das and Bikash Sinha

Variable Energy Cyclotron Centre, Department of Atomic Energy,
1/AF Bidhan Nagar, Calcutta 700 064, India

Helium content at the thermal springs at Bakreswar, near Calcutta, was observed to vary. These variations appear correlated to seismic perturbations. The position and distance of epicentre cannot yet be predicted from such correlation.

THERE is adequate evidence that the variations in the relative abundance of the constituents of terrestrial gas have certain degree of correlation with the perturbations within the mantle as well as the crust of earth¹. A recent report has indicated that there was a ten-fold increase in the radon content in bore hole gas prior to the earthquake at Kobe, Japan². Anomalous high helium concentrations have also been reportedly observed in well waters and soil gases preceding an earthquake^{3,4}.

It is well established by now that noble gas such as helium and radon interact weakly with matter; thus, it is expected that there will be pronounced variations in their relative abundance for such perturbations just mentioned, compared to their chemically reactive counterparts, such as nitrogen and methane. In the case of radon on account of chemical non-equilibrium and short recoil length, the host rocks incorporating the parent Ra-226 migrates rather large distances in water and in soil⁵. However, its relatively short decay time (3.82 days) inhibits any substantial concentration, so that very marginal radon content contribute above background value⁶. Over the last several years, we have been observing large fluctuation in helium concentration in the

natural gas emanating from thermal springs⁷. Three mechanisms have been suggested so far to account for the anomalies observed for the constituents of the soil gas in seismic-induced disturbances: (i) relative increase in heat flow that enhances gas concentrations near the surface^{7,8}, (ii) stress-induced pore collapse resulting in an upward flow of deep-seated gas⁹, (iii) stress-induced microfracturing leading to an increase in outgassing¹⁰. The collected sample of natural gas issuing from thermal springs was measured analytically by two separate techniques. A gas chromatograph operational at Bakreswar, the site of investigation (about 200 kms from Calcutta), of Variable Energy Cyclotron Centre was used to determine the relative abundances of helium and associated gases. Furthermore, the relative abundance of helium was determined by an absolute method based on the technique first developed by Frost¹¹.

We found the helium abundance at Bakreswar to be a variable quantity in general. The computed average of helium abundance, taken from recorded data of the diurnal readings for a five-year period, 1987-1991 was around 1.8%. We call this the characteristic 'helium index' for the spring. The normal value of the emanation rate during the quiescent state was close to the above figure with approximately $\pm 0.2\%$ variation. However it had been observed that the index began to fall very gradually two to three weeks prior to an impending seismic disturbance, known as earthquakes. The index tended to reach the minimum value four to five days before the triggering of the quake. This scenario was immediately followed by a sharp rise in the index, reaching its highest value two to three days prior to the occurrence of the quake, the peak value being two to three times the minimum value. Indeed, the helium content increased to 7.3% immediately prior to the volcanic eruption at Barren Island in July 1991 (ref. 12).

The measured magnitude of the helium concentration at Bakreswar for October in 1991 is plotted in Figure 1; corresponding data for January in 1992 is in Figure 2 and for the subsequent month of April 1992 is shown in Figure 3.

It was generally seen that the profiles had an irregular oscillatory pattern. This is expected since the helium contained in any underground environment is at best in a fragile state of equilibrium. It should also be mentioned that the presence of other diluting gases such as N₂ and CH₄ affected very feebly the outflow of helium as observed by Reimer⁴ in soil gas. For large scale deviations ($d > 3\sigma$) one has to thus look for catastrophic causes such as earthquakes as suggested by Scholz *et al.*¹³. In order to judge the long term and background behaviour of helium changes, emission graphs for the period June 1991 to October 1991, January 1992 to July 1992 and January 1993 to October 1993 (Figures 4-6) are given. The spring gas was collected

Figure 1. Variations of diurnal helium content during October 1991. The peak on 18 October precedes the Uttarkashi Earthquake on 20, 1991.

Figure 3. Helium variations for April 1992. The peak on 12 April corresponds to tremor at Shillong on 15 April 1992.

Figure 2. Helium variations for January 1992.

Figure 4. Temporal variations of helium in 1991 from June to October.

beneath a water column about 1.2 m. One can therefore preclude effects caused by meteorological conditions such as atmospheric pressure, wind speed, precipitation and temperature variations. As the springs lie in a relatively secluded area, influence of other non-tectonic factors such as mining, industrial activity, dam building or even water pumping is unlikely.

Our observations tend to indicate that the gas anomalies are reflected even at large distance from the centre of the quake. However, we could not correlate the observed increase in helium on January 21, 1992 to any specific tremor. Nonetheless, the peak may well be a manifestation of the reported seismic disturbances in Ionian sea; the Kamchatka peninsula and Japan's Honsu Island around January 23–25, 1992. It is also known that a change in strain associated with an earthquake by only 10^{-8} will lead to a change in the helium content¹⁴. Such gas anomalies and seismic disturbances are possible

incidental results of the same cause, the strain changes that take place within the earth's crust. Because of the large disparity in the magnitude of the energies involved, gas anomalies show up much earlier.

In some cases fluctuations as high as six to seven times the standard deviations have been noticed. It has not been possible so far, as mentioned, to predict with reasonable precision the distance of the epicentre of the quake or its location with relation to the thermal spring. One can only predict two or three days prior to the triggering of an earthquake somewhere! Work is in progress to estimate the radial distance of the epicentre from the spring site through multiple observation points. Although, as yet, there is no total one to one correspondence between earthquake and anomaly occurrences, we would venture to predict the following about the possible increase in the relative abundance of helium scenario just before the earthquake, admittedly rather

Figure 5. Temporal variations of helium in 1992 from January to July.

Figure 6. Temporal variations of helium in 1993 from January to October.

speculative, but interesting. Gradual accumulation of stress within the rock structure results in rise of pore pressure. The typical precursor of earthquakes, in general, is a steady rise in the pressure around the epicentre of the quake, at or around a yet unknown critical pressure of the system. Rather like more familiar phase transition of the system at a critical pressure essentially gives in with a sudden release of the pressure. With the rise of pressure the amplitude of the elastic shocks propagating around the centre increases as it approaches towards the triggering point. The shock waves, associated with the pressure release is the quake. With release of the pressure the helium stored in the rock matrix, aquifer or produced *in situ* tends to escape in larger volume as observed. The shocks travel a fairly large distance indeed, the very characteristic of helium is such that sources of helium turn out rather sensitive even at a very large distance. The speculative scenario, just prescribed has analogies with the bounce of supernova explosion or even head shocks or slide splash in nuclear physics^{15,16}; a geological analogue in large scale is yet to be worked out.

Modelling of aeromagnetic anomaly and its implication on age of emplacement of ultramafic-mafic-alkaline complex at Jasra, Assam

D. Atchuta Rao, G. D. J. Sivakumar Sinha and H. V. Ram Babu

National Geophysical Research Institute, Hyderabad 500 007, India

The aeromagnetic anomaly around Jasra in Assam, based on which the Atomic Minerals Division had discovered an ultramafic-mafic-alkaline carbonatite complex¹ has been modelled. Inferred direction of magnetization of the source body suggested the age of emplacement of the source to be around Jurassic period which is correlated with the time of breaking up of the Gondwanaland and the northward drift of the Indian plate and crustal upheavals.

THE aeromagnetic survey carried out by the National Geophysical Research Institute (NGRI), over an area of about 14000 km², covering parts of Garo hills, Shillong plateau, and Khasi hills region of Meghalaya and Assam

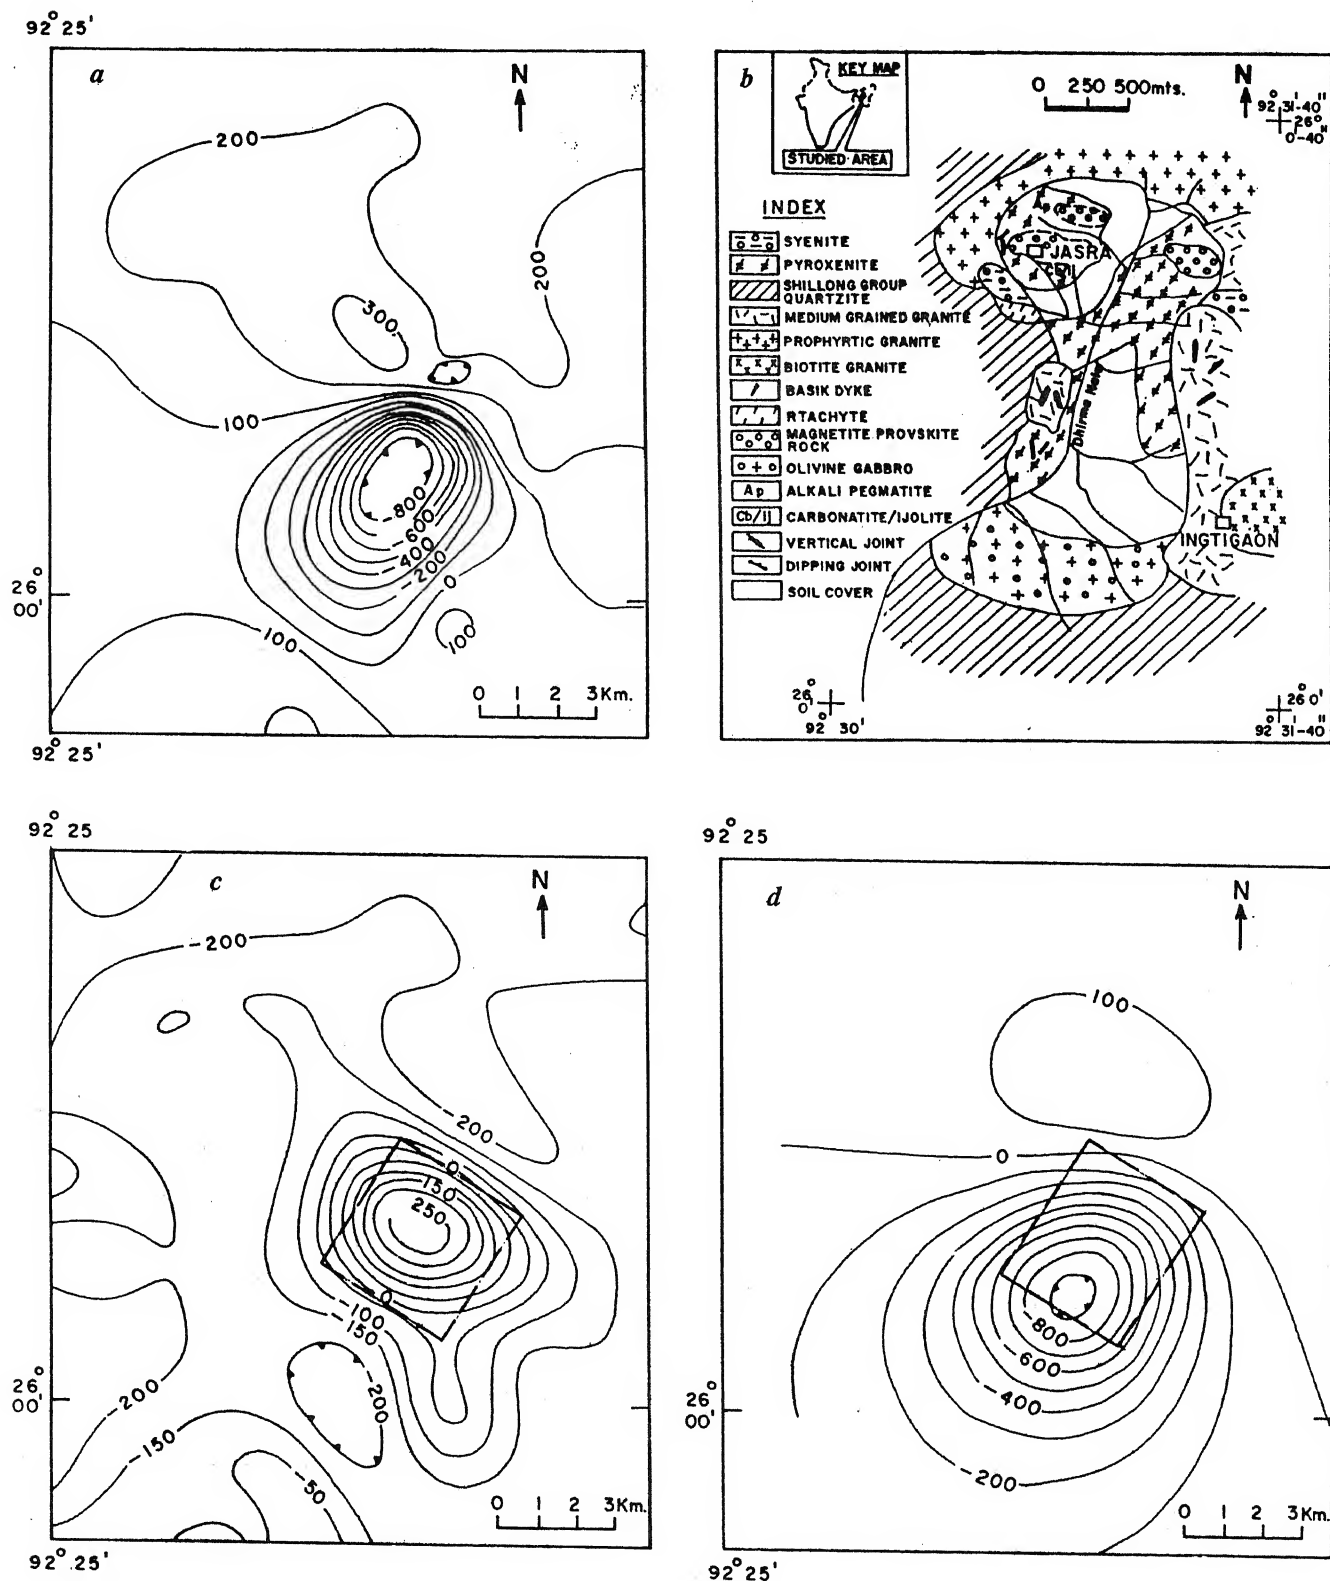

Figure 1a-d. a, Aeromagnetic anomaly around Jasra; b, geological map of Jasra area (after Mamallan *et al.*¹); c, the complex gradient map of Figure 1a showing the approximate boundaries of the source; and d, model anomaly of the interpreted parameters.

has brought out a number of important magnetic anomalies and structures. The recommendations suggesting important locations for mineral exploration were submitted as a technical report² to the North Eastern Council (NEC). One of the important aeromagnetic anomalies recommended for ground followup is the region around Jasra in Assam for the possible occurrence of ultramafic suite of carbonatite/pyroxenite rocks similar to those occurring in the Sung valley. The survey was carried out with a rubidium vapour magnetometer, designed and fabricated by the NGRI, and this region was flown on lines spaced at one kilometer apart at an altitude of 1380 m above sea level. The aeromagnetic anomaly around Jasra (after removing the IGRF) recommended for ground follow up is shown in Figure 1 a.

Based on the clues provided by aeromagnetic data and Landsat-TM imagery, the ground follow up work by the geologists of the Atomic Minerals Division (AMD) led to the discovery of an ultramafic alkaline (carbonatite) complex at Jasra, Assam and was described as a new find¹. This complex (Figure 1 b) consists dominantly of pyroxenites (with layers of titanomagnetite) with subordinate amounts of syenitic, alkali gabbroic bodies and very minor veins of ijolite, carbonatite and basic dikes. The pyroxenite body, together with other magnetizable minerals, produced an intense aeromagnetic anomaly described in the following.

The aeromagnetic anomaly associated with this complex shown in Figure 1 a, consists of a dominant low of about 800 nT amplitude with a small high on its northern side. The shape of the anomaly is not normal for this latitude for magnetization by induction and therefore suggests the presence of remanant magnetism in the source body. To infer the nature of the causative source and its magnetization, modelling of magnetic data has been done. The approximate outline of the source has been delineated from the 'complex gradient' map (Figure 1 c). The edges of the causative source appear as maxima on 'complex gradient' maps for wide and shallow sources; and for sources whose depth to top is roughly equal to the half-width, the half-maxima positions delineate the boundary of the source³. Modelling results indicated that the depth (1500 m below flight height) to the top of the source is roughly equal to the half-width of the source. Therefore, in the present case, the outline of the causative source is located at the

half-maxima positions of the complex gradient map and is marked on Figure 1 b. Interpretation of the north-south principal profile by using the 3-D vertical prism model provided the depth to the top, width and the magnetization of the source. The model anomaly of the interpreted parameters is shown in Figure 1 d. The depth to the top of the source was inferred to be about 70 m below the ground surface. The dimensions of the source obtained from the modelling are 2.5×3.5 km and appear to be larger than the outcropping complex. This may be due to widening of the source at depth. The intensity of magnetization is about 500 nT. The direction of magnetization (I) of the source is obtained as -63° . This parameter can be used to calculate the palaeolatitude (λ) by using the standard relation $\tan(I) = 2 \tan(\lambda)$. In the present case,

$$\tan(-63) = 2 \tan \lambda$$

$$\therefore \lambda = -45^\circ = 45^\circ \text{S}.$$

The palaeolatitude of -45° suggests that this part of the continent was located at 45° south latitude (i.e. in the southern hemisphere) at the time of emplacement of this intrusive source. The position of the north-eastern India at this latitude corresponds to the Jurassic period⁴ (125–175 my), which is in agreement with the reported ages⁵ of 156 ± 16 Ma and 149 ± 5 Ma for the alkaline magmatism in this region and is correlated with the time of breaking up of Gondwanaland and northward drift of the Indian plate and crustal upheavals.

Further evidences of homeotic transformation in anuran tadpoles

Kakoli Das and S. K. Dutta

Department of Zoology, Utkal University, Bhubaneswar 751 004, India

In this communication we report the development of ectopic supernumerary limbs (ESLs) from the cut ends of tails of *Bufo melanostictus* (Anura: Bufonidae), *Microhyla ornata* (Anura: Microhylidae) and *Hoplobatrachus tigerinus* (Anura: Ranidae) tadpoles exposed to various concentrations of vitamin A (Palmitate) solution. In addition, several other deformities (tail abnormality, outgrowth on tail tips, etc.) have also been recorded. Like the previous reports, the ESLs are all hindlimbs and comprise of both normal and abnormal hindlimb elements.

THE effect of tail tissue, its skin epidermis and dermis on the limb regeneration of salamanders *Triturus viridescens*¹ and *Siredon mexicanum*² had enough basis to influence researchers working on amphibian regeneration. Based on this, Iten and Bryant^{3,4} reported the stages of tail regeneration and regeneration from different levels along the tail of the newt, *Notophthalmus viridescens*. Preceding the above finding was the report by Niazi and Saxena⁵ highlighting the effect of vitamin A on tail regeneration of anuran tadpoles. Moreover, the reports on the inhibiting influence of vitamin A on tail regeneration in *Bufo andersonii*⁶, *Xenopus laevis*, *Notophthalmus viridescens* and *Ambystoma mexicanum*

tadpoles⁷ confirmed the above report. In contrast, the inhibiting influence of vitamin A was prevented by the use of sulphadiazine⁸ showing the antagonistic effects on vitamin A for tail regeneration of *B. melanostictus* tadpoles.

The finding demonstrating the development of ectopic supernumerary limbs (ESLs) at the site of tail amputation in *Uperodon systoma*⁹, was an ultimate breakthrough on vitamin A effect on the regenerating capacity of tails in anuran tadpoles. The phenomenon known as homeotic transformation was the first report in vertebrates, mediated through vitamin A. Thereafter, homeotic transformations have been reported in *Polypedates maculatus*¹⁰⁻¹⁴ (rhacophorid), *Tomopterna rolandae*^{13,15,16} (ranid), *Rana limnocharis*¹³ (ranid), and *Rana temporaria*¹⁷ (ranid) tadpoles exposed to various concentrations of vitamin A solution. Here we report additional information on homeotic transformation in three other anuran species.

The tadpoles of *B. melanostictus*, *M. ornata* and *H. tigerinus* used in the experiment were reared in the laboratory from egg clutches collected from breeding grounds during July 1994. Amputation was performed on tadpoles at Gosner stage 26 (hindlimb bud stage)¹⁸. The tadpoles were narcotized in 1:400 solution of MS222 in conditioned water. 128 of *B. melanostictus*, 60 of *M. ornata* and 9 of *H. tigerinus* tadpoles were used in the study. After tail amputation, the tadpoles were transferred to amphibian ringer and kept for about 10 min for recovery from anaesthetic condition and for

RESEARCH COMMUNICATIONS

coagulation of blood at the amputation site. For each species, the control group consisted of 5 tadpoles, reared in 500 ml of conditioned water after tail amputation. The rest of the tail amputated tadpoles were treated with various concentrations of vitamin A solution for different time intervals. After exposure to vitamin A solution, the tadpoles were reared in conditioned water

until death or emergence of forelimbs. Table 1 shows the number of tadpoles, concentration of vitamin A solution and hours of exposure.

In *B. melanostictus* (Figure 1 a-f), the control tadpoles metamorphosed within 15 days of amputation and there was no structural abnormality in both the fore- and hindlimbs. Some of the experimental tadpoles survived up to a maximum of 96 days in 24 h exposure to vitamin A solution. However, none of the tadpoles metamorphosed and they died at some stage of development, during the period when a tail stump differentiated into a hindlimb. Out of 128 experimental tadpoles (Table 1), 25% regenerated normal tail. The rest developed abnormal tails with various kinds of morphological abnormalities. The regenerated tails had tail fins that did not cover the tail tip and there was cellular mass protruding from the tip of the axial tissue. In some, the dorsal fin extended along with the tail musculature curving downwards, while the ventral fin narrowed and was suppressed from where the tail tissue began its curve. Others had bent tail fins, ventral fin broader and covering the tail tip, while the dorsal fin narrowing mid way. A swelling that developed in the tadpoles at the amputation site had reduced tail fins. In addition to the abnormal tail tips, the fore- and hindlimbs were also deformed. The hindlimbs had reduced shank and the forelimbs were without distinct humerus, radio-ulna and with 6 fingers. There was also the development of extra paired hindlimbs at the site of the growth of normal hindlimbs.

Ectopic development of limbs at the amputation site was observed in 2.3% of experimental tadpoles. In addition, there was also regeneration of tail with laterally curved axial tissue and tail fins along with the development of ESLs. The ectopic hindlimbs also developed in pairs having distinct thigh, shank, ankle and digits. In some, the shank and ankle were suppressed, thighs fused and the 4th and 5th digits joined (Table 2).

In *M. ornata* (Figure 2 a-d), the control tadpoles metamorphosed within 40 days of amputation, without exhibiting any abnormality. The experimental tadpoles (Table 1) had a maximum survival period of 86 days and 65% of them developed normal tails while the rest regenerated abnormal tails. The abnormalities included

Figure 1 a-f. *Bufo melanostictus*. a, Development of cellular outgrowth and a pair of abnormal ESL with suppressed shank and ankle (exposure: 10 IU vitamin A for 120 h); b, Development of three normal ESLs (exposure: 10 IU vitamin A for 96 h); c, Development of a pair of ESL at the limb bud stage, along with a swelling (exposure: 10 IU vitamin A for 96 h); d, Development of a pair of abnormal ESL with jointed thighs, 4th and 5th digits of one ESL fused (exposure: 15 IU vitamin A for 72 h); e, Development of abnormal tail tip, the hindlimbs with reduced shank and the forelimbs without distinct humerus, radio-ulna and with six fingers (exposure: 10 IU vitamin A for 96 h); f, Development of abnormal tail tip and extra pair of hindlimb at the site of the growth of normal hindlimbs (exposure: 10 IU vitamin A for 96 h).

Table 2. Analysis of ESLs of *Bufo melanostictus*, *Microhyla ornata* and *Hoplobatrachus tigerinus*

Species	Group	Number of tadpoles with ESLs	Number of ESLs	Normal ESLs	Abnormal ESLs	Abnormality/normality of the ESLs
<i>B. melanostictus</i>	10 IU (96 h)	2	(i) 1 (ii) 3	— 3	1 —	Limb bud, thigh, shank ankle and digits, well developed
	10 IU (120 h)	1	2	—	2	Shank and ankle, suppressed in both the ESLs
	15 IU (72 h)	1	2	—	2	Jointed thighs digits 4th and 5th attached
<i>M. ornata</i>	30 IU (72 h)	1	4	2	2	Jointed thighs
	40 IU (48 h)	1	2	2	—	Distinct thigh shank, ankle and digits
<i>H. tigerinus</i>	20 IU (96 h)	1	2	—	—	Limb bud

growth of irregular cell mass at the amputation site, deshaped tail fins, loss of fins and small outgrowths ventro-laterally on the regenerating tail, and development of ESLs (3.3%) at the site of amputation. The ESLs besides having distinct thigh, shank, ankle and digits also had fused thigh (Table 2).

In *H. tigerinus* (Figure 3 a-f), the control tadpoles metamorphosed within 25 days of amputation and like the other two species, there was no abnormality in their limb or tail. Like the controls some of the experimental tadpoles survived for a maximum of 25 days, but none of them metamorphosed (Table 1). The abnormalities in tail regeneration included the development of irregular cell mass at the site of amputation, deshaped tail musculature and fins and development of ESLs. The abnormality was 66.7% and out of the total abnormal tadpoles, 11.1% showed ectopic limb development covered externally by the swellings (Table 2).

The above results indicate variation in the time period of completion of metamorphosis in the control groups and this is species-specific. In the experimental tadpoles, the maximum survival time was also recorded for *B. melanostictus* exposed to 10 IU/ml vitamin A solution for 24 h. Besides, the highest percentage (75%) of abnormality was also recorded for the species. The number of ESLs was the highest (4) in *M. ornata*. All the tadpoles of *H. tigerinus* sustained a high dose of vitamin A (20 IU) solution for a longer period and mortality was recorded from the 20th day of treatment.

Figure 2 a-d. *Microhyla ornata*. a, Regeneration of a curved tail and deshaped tail fin (exposure: 30 IU vitamin A for 72 h); b, Cellular outgrowths at the amputation site (exposure: 30 IU vitamin A for 72 h); c, Development of a pair of ESLs (exposure: 40 IU vitamin A for 48 h); d, Development of 4 ESLs; one pair normal and the other pair abnormal with jointed thighs (exposure: 30 IU vitamin A for 72 h).

Figure 3 a-f. *Hoplobatrachus tigerinus* tail amputated tadpoles, exposed to 20 IU vitamin A solution for 96 h. *a*, Development of a cell mass and folding of the tail fins at the amputation site; *b*, A small swelling at the amputation site covered by the tail fins; *c*, Loss of fins at the tail tip; *d*, Abnormal tail regeneration, with a small outgrowth at the tail tip; *e*, Development of irregular cell mass at the tail tip; *f*, Development of irregular cell mass with ESLs (minute).

The experimental tadpoles of all three species exhibited delayed growth as reported earlier for *R. temporaria*¹⁷ (ranid) and *P. maculatus*¹⁴ (rhacophorid) tadpoles. In addition, the mortality was not time-dependent and there was no correlation between mortality and the duration of exposure to vitamin A solution, unlike that reported for *P. maculatus*¹⁴, *B. andersonii*^{5,6} and *R. cyanophlyctis*^{6,19}.

The experimental tadpoles also regenerated abnormal

tails as reported for *U. systoma*⁹, *B. andersonii*^{5,6}, *X. laevis*⁷, *N. viridescens*⁷, *A. mexicanum*⁷, *P. maculatus*^{12,14} and *T. rolandae*¹⁵. The most fascinating finding was the development of ectopic hindlimbs in all the species. However, the percentage (4.1%) was lower than earlier reports^{12,14,17}. Vitamin A palmitate administered for at least 48 h showed the induction of limbs at the site of tail amputation in *B. melanostictus*, and *M. ornata* tadpoles. *H. tigerinus* tadpoles needed longer exposure

(72 h) to vitamin A solution. Hence, it is concluded that 48–72 h was the required duration of treatment for the development of ectopic limbs as has also been reported for *R. temporaria*¹⁷ (3 days as the threshold level) and for *P. maculatus*¹⁴ (48 h as the minimum exposure time). However, in *P. maculatus*¹², *T. rolandae*¹⁵ and *R. limnocharis*¹³ ectopic limbs developed when the exposure time was for 24 h. Thus, it can be inferred that the induction of ectopic limbs is not time-dependent as otherwise proposed by Maden¹⁷.

It has been interpreted that hindlimb development is marked by the rising levels of thyroid hormone (TH)²⁰. It is likely that during the regeneration process²¹ at the amputated site, the TH combines with vitamin A palmitate and alters the tail hox code while repressing other genes resulting in the formation of limb blastema cells, particularly the ones that give rise to hindlimb fields¹⁷.

The effect of vitamin A palmitate at the tail amputated site of tadpoles causing homeotic transformation may be attributed to the conversion of the tail blastema cells to that of limbs. This changes the positional values at the tail tip. Subsequently, rearing in conditioned water after exposure to vitamin A, reverses the polarity along the rostral–caudal axis to generate ectopic limbs²². Some of the ectopic limbs develop from cellular mass at the site of amputation and mostly in a ventro-lateral direction similar to those observed in *P. maculatus*^{12,14} and *T. rolandae*^{13,15}. This is comparable to the finding in *B. andersonii*⁶ in which continued exposure to vitamin A palmitate resulted in the folding of the fin to form a pouch at the tip of the regenerating tail. The cellular mass which is formed prior to the development of ectopic limbs may act as a reservoir for the transformed cells which needs to be investigated through histology. There was also regeneration of a complete tail that followed the growth of ESLs in *B. melanostictus* tadpoles as reported in *P. maculatus*¹², *T. rolandae*¹⁵ and *R. limnocharis*¹³. This is expected, in accordance with the interpretation schematically proposed by Bryant and Gardiner²². However, the interpretation of development of paired ectopic hindlimbs²² is contradictory to the present finding as odd number (3) of ectopic limbs has been observed in *B. melanostictus* tadpoles as was also found in *T. rolandae*¹⁵ and *R. limnocharis*¹³. Further, with the growth of an abnormally regenerated tail, there was also the development of extra-paired hindlimbs at the site from where only a single pair of hindlimb was supposed to develop. This observation was previously reported in *B. vulgaris*²³ and again in *U. systoma*⁹. These deformities could be related to the embryonal malformations caused by vitamin A²⁴. In addition to the findings on *U. systoma*⁹, *R. temporaria*¹⁷, *T. rolandae*¹⁵, *R. limnocharis*¹³ and *P. maculatus*^{10,12,14}, the present study adds further to our knowledge on homeotic transformation in anuran tadpoles.

How does the nocturnal animal, *Mus booduga*, programme its activity in response to varying durations of light and darkness?

L. Geetha

Department of Animal Behaviour, Madurai Kamaraj University, Madurai 625 021, India

Present address: Animal Behaviour Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Jakkur P.O., Bangalore 560 064, India

In the temperate zone, animals adjust to various durations of light and dark by scaling the duration of activity with the durations of light (diurnal animals) or dark (nocturnal animals). They are also capable of advancing or delaying their activity depending on the durations of light or darkness. This study examines whether tropical animals which do not normally experience much variations in durations of light and

darkness can also do the same. Experiments with the field mouse *Mus booduga* show that their behaviour with respect to scaling the durations of activity matches that of temperate animals but not so with respect to anticipating the onset of darkness. It is speculated that scaling of durations of activity (α) may not require prior experience while anticipating the onset of light or darkness (i.e. showing the appropriate phase angle difference) being a more complicated adjustment cannot be achieved without prior experience.

A fascinating aspect of animal behaviour is the impressive synchronization (entrainment) of activity/rest cycles to natural photoperiods. Thus, diurnal animals confine their activity period to the light phase (L) and rest period to the dark phase (D), while nocturnal animals do the reverse¹. This synchronization is maintained even under varying durations of light and dark in the laboratory, which may sometimes deviate considerably from the natural L:D ratios². But how do varying durations of L and D affect the durations of activity (referred to as α)? There is evidence³, for example, that chaffinches correspondingly increased their α as the duration of L was increased from 8 to 20 h. Even when wider ranges of durations of L (or D for nocturnal animals) are used (or are present under natural conditions such as in some parts of the world, for example) α shows an S-shaped curve. This means that α remains almost the same up to certain durations of light, then increases linearly with increase in light and beyond a certain point reaches a plateau⁴.

A related question is how varying durations of L and D alter the time difference (positive or negative) between the onset of L (or D for nocturnal animals) and the onset of activity. Such time difference is referred to as the phase angle difference (ψ) and may be measured as the difference between the onset of activity and onset of L (or D) (ψ_o), midpoint of activity and midpoint of L (or D) (ψ_m) or end of activity and end of L (or D) (ψ_e). Observations under naturally varying photoperiods have shown that under long day length conditions for example, diurnal animals start their activity late (i.e. have a negative ψ_o), reach the mid-point of their activity before the mid-point of L is reached (i.e. have a positive ψ_m) and reach the end of their activity a little before the end of L (i.e. have a positive ψ_e). Diurnal animals show exactly the opposite behaviour under short day conditions and nocturnal animals show similar behaviour with respect to long and short nights respectively^{4,5}.

While these phenomena (both scaling of α and phase angle difference with varying durations of L and D) have been investigated in the temperate zone, we know almost nothing about tropical animals, especially tropical mammals. Is it possible that since natural photoperiods are more or less constant in the tropics, these animals

are unable to respond in the manner described above when L:D ratios are altered drastically in the laboratory? This question motivated the present study.

Adult males of the nocturnal tropical field mouse *Mus booduga* ($n=6$) were obtained from fields near Madurai University campus (9°58'N, 78°10'E). They were maintained with *ad libitum* food and water in laboratory cages fitted with running wheels where an eccentrically placed magnet facilitated recording of locomotor activity. The rotations of the wheels were picked up by an Esterline Angus event recorder. The light intensity at the cage level during L phase was about 45 lx while absolute darkness prevailed during the D phase. The different LD duration ratios were achieved by altering the relative durations of L and D (by either lengthening a single light time (L) or a single dark time (D) as the case may be) while keeping the sum at 24 h. The various L/D ratios administered were: 22:2 h; 20:4 h;

Figure 1. Actogram showing the activity pattern of an animal subjected to differing LD ratios. Open bars indicate durations of light time and filled bars indicate durations of dark time. The intensity of light during light phase was about 45 lx and absolute darkness prevailed during dark phase.

Figure 2. Durations of activity (α) as a function of durations of darkness. Mean \pm SD values are shown.

16 : 8 h; 14 : 10 h; 10 : 14 h; 8 : 16 h; 4 : 20 h and 2 : 22 h. Only the duration of light or dark was altered and the intensity of light during L phase was kept constant. Actograms were double plotted using conventional methods (Figure 1).

This study yielded two major results. One was that α did vary with durations of D (as expected in nocturnal animal) all the way from 2 to 16 h, although the positive correlation between α and D broke down after 16 h (Figure 2). This means that these tropical nocturnal animals were able to scale their α with varying durations of D much as temperate animals are capable of doing so, although they would not be expected to have adaptations to such drastic variations in LD ratios. It is true however, that the scaling of α with durations of D broke down when the duration of D was 20 or 22 h. Here α was 8.92 ± 0.96 and 11.13 ± 0.78 respectively. This breakdown of the scaling of α at extreme D durations suggests that the scaling observed when D was varied from 2 to 16 h is in fact an intrinsic property of the entrainment mechanism rather than a simple masking effect of light. In other words, the activity of this nocturnal animal was not merely suppressed by the presence of light. If that were so, there is no reason why α should not have kept pace with D even beyond 16 h. It can also be seen from Figure 1 that the scaling of α with durations of D from 2 to 16 h was quite independent of the phase in which the animal was when the LD ratios were varied. This again argues that the observed scaling of α with durations of D was not a masking effect as masking has shown to be phase dependent^{6,7}.

The second result of this study was that the phase angle differences did not correspond to the general

Figure 3. Phase angle differences as a function of durations of darkness. a, onset (ψ_0); b, mid point (ψ_m); c, end (ψ_e). Mean \pm SD values are shown. Data not available for 10 h of durations of darkness.

pattern observed in temperate zone animals described earlier. Indeed, there was no discernible pattern in the phase angle difference whether measured as ψ_0 , ψ_m or ψ_e , with increasing durations of darkness (Figure 3). The absence of differences in phase angle in response to varying LD ratios as expected in a temperate animal is not really surprising for *Mus booduga*. Tropical animals are not expected to be exposed to much drastic variations in LD ratios and are thus not expected to have the required adaptations. The longest night in Madurai for example is 12.5 h while the shortest night is 11.4 h. Studies on the tropical bat *Hipposideros speoris* have shown that these bats do seem to anticipate the onset of darkness⁸. However, since only the natural seasonal variations in LD ratios were used in this case, the bats may be expected to be able to be adapted to such variations.

The contrasting results with respect to the observed scaling of α with durations of D and the absence of

the expected patterns of differences in phase angles with varying LD ratios in the present study, raise an interesting question. How is it that a tropical animal, not used to much variations in LD ratios (in its recent evolutionary past) can still show the same behaviour as temperate animals with respect to scaling of α but cannot do so with respect to varying the phase angles. It is interesting to speculate that scaling of α with durations of D is a simpler phenomenon not really requiring prior experience or adaptation while varying the phase angles as temperate animals do is a more complicated phenomenon which involves anticipating the onset of light or darkness. This may be dependent on prior experience or adaptation. However, this speculation is based on this single result with a tropical animal. Given the extreme paucity of information on the behaviour of tropical animals under varying LD ratios and the unusual results obtained in this study, more work along these lines on other tropical animals, diurnal and nocturnal, is sorely needed.

Potent amoebicides from plant extracts – An *in vitro* assessment with the gum-oleo-resin of *Commiphora wightii*

Poonam Kumari Sharma and Jayashri Devi Sharma

School of Environmental Sciences, Jawaharlal Nehru University,
New Delhi 110 067, India

The medicinal value of *Commiphora wightii* has been believed by tribals to be mainly due to its yield of guggulipid, which has been scientifically shown to have hypcholesteromic, anti-septic, anti-pathogenic, anti-parasitic properties. It is also used for non-specific diarrhoea and dysentery. Amoebic dysentery is a common disorder of a large number of people

in the tropics. In our studies we have reviewed the active principles of most known anti-amoebic plants. Further, we have tested the crude extracts of oleo-gum-resin obtained from *C. wightii* against *E. histolytica* NIH 200 using microdilution technique. They were found to be comparable with quassinoids; Ailanthinone and Bruceantin. The need for linkages between chemical characterization with established *in vitro* techniques is demonstrated.

AMOEBIASIS by *Entamoeba histolytica* is an important cause of dysentery. Recent global estimates indicate the increasing trend from 480 million people (excluding China) annually suffering from amoebiasis¹. The search for herbs and medicines for this scourge, from all possible sources is an ongoing exercise. Many natural products of plant origin are an important source of biologically active compounds and have potential for the development of novel antiprotozoal drugs as studied by *in vivo* and *in vitro* experimentations². Table 1 shows known anti-amoebic plants studied since the last decade for their active fractions and principles.

Commiphora wightii (Arnott) Bhand, (Burseraceae) is a small tree or large-sized shrub which produces a gum 'guggal' believed to have high medicinal value. It is commonly known as 'Indian bdellium' or 'guggal' in India³. It is found in the arid rocky tracts of Rajasthan, Gujarat, Karnataka and Maharashtra states of India; Sindh and Baluchistan states of Pakistan; Bangladesh and Arabia⁴. The trunk is knotty, outer bark comes off in rough flakes leaving an inner layer which is bright, shining and peels off in thin rolls like paper. The latex oozes out through wounds or cuts as a yellow fluid which hardens to form a golden brown, yellow or reddish brown oleo-gum-resin. Guggal gum is a mixture of 61% resin, 29.3% water, 0.6% volatile oil and 3.2% foreign matter³. Guggal gum is known for its therapeutic properties in various ailments, particularly arthritis, many vascular and neurological complications, hypercholesteremic conditions⁵, rheumatism and possesses anti-inflammatory activity⁶, in cure of ischaemic heart disease, obesity, neurological disorders, ills of syphylitic nature⁷, scrofulous infections, urinary disorders and a few skin diseases⁴. Its essential oil also possess antibacterial, antifungal and antihelminthic activity.

As one of the ingredients in 'Arogya Vardhini Bati', an Ayurvedic drug, *Commiphora* is used for the treatments of diarrhoea and dysentery in man and its efficacy has been tested both *in vitro* and *in vivo*⁸. Alcohol extract of its oleo-gum-resin was tested *in vitro* against axenic cultures of *E. histolytica* NIH 200 but proved less effective than *Curcuma zedoaria*⁹. The most optimal comparisons of other such plants which were similarly studied for their active principles are *Brucea javanica*, *B. antidysenterica* and *Simarouba amara* with quassinoids; Bruceantin and Ailanthinone as their active compounds.

Table 1. Different plants possessing antiamoebic potential along with their active fractions

Plant sps.	Family	Part used	Fraction/extract	Remarks and reference no.
<i>Allium sativum</i>	Liliaceae	Cloves	Crushed cloves	Allicin inhibits the growth of axenically cultured <i>E. histolytica</i> at 30 µg/ml provided cysteine was not present in the medium. The activity of gossypol, a polyphenolic compound was 11 and 39 times greater than those of metronidazole and emetine respectively ² .
<i>Gossypium herbaceum</i>	Malvaceae	Seed	Oil	
<i>Brucea javanica</i>	Simaroubaceae	Fruit	Petroleum ether fraction, aqueous fraction, chloroform fraction	A little activity was present in petroleum ether fraction of either species but chloroform fraction of the two was highly active ¹² .
<i>Simarouba amara</i>	Simaroubaceae	Stem	Chloroform fraction	
<i>Brucea antidysenterica</i>	Simaroubaceae	Fruit	Chloroform fraction	Rates of amoeba killings by metronidazole and bruceantin, a quassinoid, were similar at 16 to 30 fold lower water conc. of the latter ¹³ .
<i>Strychnos gossweileri</i>	Loganiaceae	Root bark	Alcoholic extract	Diploceline, a quaternary alkaloid isolated is active at 50 µg/ml on <i>E. histolytica</i> ¹⁴ .
<i>Euphorbia hirta</i>	Euphorbiaceae	Whole plant	Ethylacetate fraction	Quercitrin, a flavonoid was active as antidiarrhoeic from doses of 25 mg/kg onwards ¹⁵ .
<i>Alstonia angustifolia</i>	Apocynaceae	Root	Methanol extract	Macrocarpamine, an alkaloid was found to be the most potential antiamoebic compound but 4 times less potent than the standard drug, emetine ¹⁶ .
<i>Triclisia</i> sps.	Menispermaceae	Wood	Alcoholic extract	Armoline, isotrilobine and insularine were the most active bisbenzylisoquinoline alkaloids having IC ₅₀ in the range of 5–11 µM (ref. 17).
<i>Holarrhena antidysenterica</i>	Apocynaceae	Fruit	Alcoholic extract	Conamine, holarrhimine, conkurchine, etc. were the most active alkaloids ¹⁸ .
<i>Strychnos</i> sps.	Loganiaceae	Stem	Alcoholic fraction	Usambarine and usambarensine were the most selective alkaloids. The latter possesses activities similar to those of emetine and metronidazole ¹⁹ .

In the present study an attempt has been made to test the *in vitro* anti-amoebic potential of various crude extracts of *C. wightii* using the microdilution technique. Gum resin was collected from Ajmer district (Rajasthan) and air-dried. Gum-resin (40 g) was taken, ground and extracted with 300 ml of ethyl alcohol for 10 days at 60–80°C using soxhlet apparatus. Ethanol containing the compounds was filtered and the filtrate heated at a relatively low temperature to evaporate ethyl alcohol. The ethanol soluble portion contributes about 75% of the gum resin (28.1 g). This was followed by cold extraction using petroleum ether (60–80°C). About 150 ml of petroleum ether was added to the left compound and kept for 2 days without heating so as to enable the oils and other compounds to solubilize in it. This was heated for about half-an-hour at 30°C, filtered and the filtrate was heated up to 30°C till petroleum ether evaporated. The residue was extracted with about 200 ml of chloroform and heated at 40–50°C for half-an-hour. It was cooled down, filtered and concentrated after heating. The leftover gum in the extractor, from which compounds were extracted initially using ethanol, was taken out in a conical flask, water was added to it and kept overnight. Next day it was filtered and the filtrate was heated to evaporate water. Thus, the three extracts, viz. 9.2 g of petroleum ether (yield 32.7%, w/w), 15.3 g of chloroform (yield 54.4%, w/w) and 3.6 g of aqueous (yield 12.7%, w/w) were ready for testing. *In vitro* testing against *E. histolytica* was carried out thrice in

triplicate cultures using microdilution technique. Ethanol (50 µl) was added to 10 mg of each extract followed by 950 µl of fresh culture medium. They were further diluted twice with culture medium so as to obtain a concentration of 0.1 mg/ml. These were considered as stock solutions and from them 6 serial dilutions were prepared, as shown in Table 2, using fresh culture medium (final volume, 170 µl).

Each microtitre plate included metronidazole as a standard amoebicidal drug, control wells (culture medium plus amoebae), test wells (culture medium plus crude extracts) and a blank (culture medium only). Amoebae cell suspension 170 µl was added to the test and control wells in the plates so that the wells were completely filled (total volume 340 µl). Plates were sealed with expanded polystyrene, secured with tape and placed in an incubator at 37°C. After 48 h of incubation, inhibition of growth was assessed by measuring OD with an ELISA reader at 540 nm. When compared against the standard drug metronidazole, the chloroform extract was found twice as promising as metronidazole in its activity (Figure 1). The high content (8.24%) of chloroform extract which was taken from the original 40 g of the gum resin, and also its comparably higher activity, together makes the chloroform extract an important target for further characterization. In a separate study done, the chloroform extract of *C. wightii* was shown to contain guggulsterol I–V, guggulsterones E and guggulsterones Z¹⁹. Table 2 shows comparable effectiveness

4	0.6020	97.54	85.78	82.71	65.20

IC₅₀ for the standard drug, metronidazole = 0.43 µg/ml.

IC₅₀ for chloroform extract = 0.22 µg/ml.

IC₅₀ for aqueous extract = 0.24 µg/ml.

IC₅₀ for petroleum ether extract = 0.88 µg/ml.

Figure 1. Activity of standard drug metronidazole, chloroform extract, petroleum ether extract and aqueous extract obtained from gum-oleo-resin of *Commiphora wightii* against *Entamoeba histolytica* (NIH 200) *in vitro*. (Log of the corresponding X-axis values are given within the brackets).

of three crude extracts of *C. wightii* and the standard drug metronidazole.

The active principles from *C. wightii* have been classified into four fractions, the oleo fraction containing myrcene compounds, gum fractions A and B containing sugars and resin fraction containing sterols³. The ethyl acetate soluble portion constitutes about 45% of the gum resin, the hexane phase material constitutes about 9% of the gum resin and consists essentially of the diterpenoids, besides a small percentage of cholesterol and other unidentified compounds. Material contained in the benzene phase constitutes about 14% of the gum resin²⁰. Mukolol, a new diterpene alcohol, had been determined and isolated from the gum resin of *C. wightii*²¹.

Since alkaloids and quassinoids of *C. wightii* have not been studied extensively by these standard techniques, an effort should be made in this direction. The arduous and longstanding sporadic attempts in defining the principles of trying to find plant extract efficacies are in many ways incomplete. Some of these principles can even include the subjective but to some extent justified

beliefs of tribals and non-allopathic methods of treatments. They need to be reviewed and correlated with better defined standards and refined further to include biologically active fraction with their characteristics.

Determination of hypoglycemic activity in *Morus indica* L. (mulberry) shoot cultures

S. M. Kelkar, V. A. Bapat*, T. R. Ganapathi*,
G. S. Kaklij, P. S. Rao* and M. R. Heble*

Radiation Biology and Biochemistry Division and
*Biotechnology Division, Bhabha Atomic Research Centre,
Mumbai 400 085, India

The aqueous extract from the leaves of shoot cultures of two elite varieties of mulberry, viz. S-34 and S-36, showed the presence of hypoglycemic activity when fed to the diabetic rats. The hypoglycemic activity of the extracts of leaves from the shoot cultures was higher and better as compared to the field-grown plant leaves. Based on these results, the usefulness of *in vitro* plantlets of mulberry, as a source of antidiabetic compound (S) is discussed.

MEDICINAL plants and their extracts have gained increasing importance over the past several years, since they can be used as a source for the preparation of herbal drugs¹. Studies on *in vitro* shoot cultures of medicinal plants have shown the presence of known and new pharmacologically active compounds².

Mulberry is valued for its foliage which constitutes the chief feed for silkworms. Besides its use in silk industry, mulberry leaves are useful as cattle fodder. They are nutritious and palatable and are known to improve milk yield when fed to dairy animals³. Analysis of mulberry leaves collected from different parts of India has revealed the presence of proteins, carbohydrate, calcium, iron, ascorbic acid, β -carotene, vitamin B-1, folic acid and vitamin D. All these are essential for the growth of the silkworm⁴.

Apart from their use as animal and insect feed, mulberry leaves have been shown to possess medicinal applications as they contain diuretic, hypoglycemic and hypotensive agents³. Thus, non-toxic mulberry leaves would be an ideal source for testing the presence of hypoglycemic activity. The present report describes results of the presence of hypoglycemic activity in extracts of leaves from *in vitro* shoot cultures and field-grown plants of mulberry.

Shoot cultures of mulberry (*Morus indica* L. var. S-34 and S-36) were used for experiments. The cuttings from mature trees of these two varieties were collected from Central Silk Research and Training Institute, Mysore, and were planted in experimental station at Trombay, Mumbai. These two varieties were selected on the basis of their good quality foliage throughout the year, their amenability to vegetative propagation with fast regenerative capability, high nutritional value and more resistance to stress, diseases and pests⁵. From such field-grown plants, buds which sprouted within 4–6

weeks were used for the establishment of shoot cultures. Auxiliary buds were surface-sterilized with 0.1% HgCl_2 for 5 min. After rinsing 5–6 times with sterile water the auxiliary buds were cultured aseptically on medium⁶, supplemented with IAA ($5.71 \mu\text{M}$) containing 3% wt/vol sucrose on which they produced extensive shoots and roots. The detailed protocol for establishment of shoot cultures from such plantlets has been described earlier⁷. Among these two varieties, S-36 grew very well on solid medium (i.e. MS supplemented with $22.10 \mu\text{M}$ BAP), whereas S-34 variety produced ample shoots in liquid medium of the same composition. From a single cultured auxiliary bud of S-34, within a period of three weeks 30–35 shoots were formed. The pH of the medium was adjusted to 5.8 before gelling the medium with 0.8% agar (HiMedia, 201 HiMedia Laboratories Pvt Ltd, Mumbai, India). Both solid and liquid cultures were maintained in a culture room at $25 \pm 2^\circ\text{C}$ at a relative humidity of 50–60% and were exposed to continuous fluorescent light (ca. 1000 lux). The liquid cultures were kept on a shaker at 70 rpm for continuous agitation.

The leaves from field-grown S-36 or S-34 variety were cleaned with water, blotted, weighed and homogenized in ice-cold water, first in mixer-grinder (Sumeet Company, Mumbai, India) and then in Tri-R Stir-R homogenizer (model S63C, Tri-R Instruments Inc., NY, USA). Similarly leaves from shoot cultures of S-36 or S-34 variety growing in test-tubes were taken, weighed and homogenized. All extracts were filtered through nylon wire mesh and the aqueous suspensions, having pH 6.1 to 6.4, were used for the bioassay.

Normal male Wistar rats weighing 190–210 g maintained on stock laboratory diet were used. The diet constituted 70% wheat, 20% bengal gram, 4% yeast, 5% fish meal, 0.75% til oil, 0.25 shark oil (corresponding to 60% carbohydrate, 30% protein, 5% fats/oils, 5% fibre), supplemented with vitamins and minerals mixture.

Diabetes was induced in rats by a single intramuscular injection of streptozotocin (60 mg of STZ/kg body wt) after 24 h of fasting⁸. The diabetic animals were stomach-fed with extracts using catheter tubes over a period of 3 days.

The blood was collected from tail-vein before feeding, 2.5 h after first feeding and after 5th feeding on the 3rd day. During this period (otherwise also), rats were maintained on the diet stated above. The blood was deproteinized⁹ and glucose was estimated immediately by Glucofix kit¹⁰ (Minarini Diagnostics, Italy) in protein-free supernatant. The hypoglycemic activity is expressed as percent reduction in blood glucose. Data was subjected to statistical analysis using Student's *t* test.

The aqueous extracts of mature leaves from field-grown S-36 variety exhibited hypoglycemic activity in STZ-diabetic rats within 2.5 to 3 h as shown in Table 1. The extent of reduction in blood glucose level decreased

RESEARCH COMMUNICATIONS

Table 1. Hypoglycemic activity in leaf-extracts of S-36 and 34 varieties of *Morus indica* grown in field or in cultures

Source	Maturity	Dose/feed	n	Reduction in blood glucose (%)		Reduction/g (%)*	
				2.5 h	3rd day	2.5 h	3rd day
S-36							
FGL	Old	250	15	26.5 ± 1.2	14.9 ± 1.4	21.2	11.9
FGL	Young	260	11	nil	nil	—	—
TCL	Old	130	13	16.6 ± 1.4	26.0 ± 1.2	25.6	40.1
TCL	Young	200	11	nil	nil	—	—
S-34							
FGL	Old	300	11	37.7 ± 1.2	9.3 ± 0.9	25.1	6.2
TCL	Old	700	15	34.4 ± 1.3	40.2 ± 1.1	49.2	57.5

The dose is indicated as extract corresponding to mg of leaves/feed/animal. Total of five feeds were given. Diabetic rats were 8–10 post Stz-days. Zero hr blood glucose were exceeding 550 mg/dl and were taken as control. *P* values were <0.005 for S-36 and <0.001 for S-34 variety compared to zero hr blood glucose. FGL: field- grown leaves; TCL: leaves of shoot cultured plants; Young leaves – weight < 1.0 g/leaf. Old leaves – weight > 1.5 g/leaf.

*per gram of leaves.

on the 3rd day in spite of giving feeds twice daily. This partial loss of hypoglycemic effect could possibly be attributed to rapid metabolism of the compound(s) responsible for the observed effect. However, the extract of young leaves from field-grown S-36 variety did not show any effect. The presence or absence and concentration of any bioactive compound are known to be influenced by the age of tissue, age of plant, season and location or area of plant. The difference in hypoglycemic activity of old and young leaves in the present study, could be attributed to the age of leaves. Nearly half the dose of leaves from cultured plantlets of S-36 variety caused 16% reduction in blood glucose after 2.5 h which increased to 26% on the 3rd day.

The leaves from field-grown S-34 variety showed 38% reduction in blood glucose after 2.5 h which decreased to nearly 9% on the 3rd day (Table 1). This decrease was similar to that observed with extract of S-36 variety leaves stated above. It can be seen that feeding 700 mg of extract of leaves of S-34 shoot cultures resulted in 34% reduction in blood glucose after 2.5 h which increased to 40% after 3 days feeding.

The total number of feeds were the same for all the groups, though the amount in each feed varied. Therefore, comparative hypoglycemic efficacy per gram of field-grown and *in vitro* shoot cultured leaves is given in Table 1. It is evident that the response of leaves from shoot cultures of both S-34 and S-36 was better than field leaves possibly due to the *in vitro* and *in vivo* stability of compounds responsible for blood glucose reduction. The retention of hypoglycemic response up to 3rd day in case of leaves from shoot cultures is in contrast to that observed for leaves from field grown plants of the same variety. This could presumably be ascribed to the differences in the nature and/or composition of hypoglycemic compound(s) present in natural/field grown plant and cultured plantlet(s).

The foregoing observations bring out for the first time the presence of hypoglycemic activity in field-grown mulberry leaves using diabetic rats as a model for testing. Moreover, hypoglycemic activity from cultured leaves appeared to have better efficacy. It is difficult to compare the efficacy of the extract used in the present studies with the known sulphonyl ureas employed in practice. Nevertheless, a gross comparison can be made. Feeding of chlorpropamide (Diabenese, Pfizer Company) mixed in a diet at a dose of 90–100 mg/rat/day for 5 consecutive days resulted in 50% reduction in blood sugar in STZ-diabetic rats⁸. However, feeding of 700 and 130 mg extract of leaves from plantlets of S-34 and S-36, for 3 days caused 40% and 26% reduction in blood glucose respectively. In fact, the efficacy may be significantly more after purification of the compound(s) from the extract. These studies are underway.

Use of revegetated coal mine spoil as source of arbuscular mycorrhizal inoculum for nursery inoculations

V. S. Mehrotra

Department of Botany, University of Allahabad, Allahabad 211 002, India

The present investigation examines the potential use of revegetated coal mine spoil as a source of arbuscular mycorrhizal inoculum for inoculating nursery seedlings. Rhizosphere soils of five tree species were used as sources of mycorrhizal inoculum. Soils contained seven spore-forming species of AM fungi. The substrate used in the pot experiment was a mixture of unsterilized coal mine spoil (without any mycorrhizal propagule) and autoclaved sandy loam soil. *C. siamea* and *D. indica* were used as the test plants. Measurements were made of shoot and root biomass, P uptake, per cent mycorrhizal infection and spore population of AM fungi. Growth measured as shoot and root dry weight was significantly higher in seedlings inoculated with soil inoculum from under *D. sissoo*, *C. siamea*, *D. indica* and *A. indica*. *A. scrobiculata* was found to be the best fungus in terms of root colonization ability and effectiveness to promote P uptake and growth in plants. A consistently poor growth response of the seedlings to soil inoculum from under *E. hybrid* was due to the ineffective association formed by *G. geosporum*. Whilst spores of *S. calospora* were not present in the rhizosphere soils of *D. indica*, they were formed in *C. siamea* pots inoculated with the same soil. This indicates that *S. calospora* also persisted in the soil in the form of propagules other than the spores. The results of this study justify the use of revegetated coal mine spoil as an effective and economical source of endomycorrhizal inoculum for inoculating nursery seedlings.

REVEGETATION and reclamation of mine spoils has been problematic because of the poor physical conditions, extremes of temperature and pH, low levels of organic and inorganic nutrients, toxic levels of heavy metals and lack of beneficial micro-organisms. Spreading top soils, a source of some beneficial organisms before revegetation may be helpful in establishing vegetation on mine spoils¹, but this has met with limited use because of the high costs of transportation of top soils. Reclamation of mined lands, therefore, requires innovative approaches that reduce the cost and increase the chances of success of plant establishment and survival². Plant establishment on mine spoils can be facilitated by endomycorrhizas formed by arbuscular mycorrhizal (AM) fungi³, as they are particularly effective in making positionally unavailable nutrients available through greater exploration of soil volume⁴. Introducing mycor-

rhizal fungi in freshly stockpiled overburden spoil would require planting of nursery seedlings inoculated with propagules of AM fungi. Use of this method will be most effective if plants are inoculated with AM fungi which are known to form mycorrhizal associations on mine site⁵. Differences in AM endophytes in their ability to colonize roots and improve growth⁶ and P uptake⁷ in plants have been observed. Native AM fungi have been found to be more effective than introduced fungi in improving the plant growth^{8,9}. Studies on growth responses of different host species to AM fungi in coal waste¹⁰ have concluded that research on value of endomycorrhizas to survival and growth of plants should be concentrated on testing a variety of endophytes which have persisted on the bituminous coal mine spoil, in order to find an ecologically adapted AM endophyte.

AM fungi are obligate symbionts and artificial medium for their independent growth has not been identified yet. Plants must be inoculated with inoculum produced on living roots in open pot cultures. Production of large amounts of mycorrhizal inoculum in pots for large-scale nursery applications is not economically and practically feasible. Rhizosphere soils of different tree species colonizing old mine spoils at the mine site, may prove to be valuable sources of inoculum of ecologically adapted strains of AM fungi². In order to use revegetated mine spoil successfully, it is necessary to test its effectiveness as a source of mycorrhizal inoculum on different plant species. Moreover, an understanding of how individual fungi colonize roots, survive and effect P uptake from mixed populations on revegetated mine spoils will also be valuable in assessing the contributions of AM fungi under nursery conditions¹¹.

The aim of this study was to examine the potential use of revegetated coal mine spoil from under different tree species as a source of endomycorrhizal inoculum for inoculating seedlings of two nitrogen-fixing tree species, *Cassia siamea* Lamk. and *Derris indica* (Lam.) Bennet. suitable for restoring degraded tropical areas.

The substrate used for the pot experiment was a mixture of unsterilized coal mine spoil obtained from the freshly stockpiled overburden at Jayant open cast mine site (E 82°36'40"–82°41'15" and N 24°6'46"–24°11'5") of Northern Coalfields Ltd, Singrauli, India and autoclaved sandy-loam soil (2 : 1 v/v). Bioassay test using corn (*Zea mays* L.) plants showed that the coal mine spoil had no mycorrhizal propagules. The substrate soil had the following chemical properties: pH, 6.2; OC, 1.33%; EC, 0.27 dsm⁻¹; P, 2.2 mg kg⁻¹; K, 46.2 mg kg⁻¹. Five kg of air-dried soil was transferred to each 20 cm wide and 14 cm high clay pots, watered thoroughly and allowed to drain for 1 week. *C. siamea* and *D. indica* seeds were surface-sterilized in 10% solution of sodium hypochlorite for 2 min, soaked in sterile water for 24 h and sown in pots containing sterilized sandy-loam soil.

RESEARCH COMMUNICATIONS

Rhizosphere soils (20 cm below soil surface) of five tree species, *Dalbergia sissoo* Roxb., *Cassia indica* A. Juss. and *Eucalyptus* hybrid growing on a 5-year-old reclaimed overburden at Jayant coal mine site, were used as sources of mycorrhizal inoculum. Soil samples were kept at room temperature¹² for one month before use. Rhizosphere soils were subjected to wet sieving and decanting¹³ and spores were collected and counted on grids drawn on filter paper. Spores were identified to species using current taxonomic guide¹⁴ and original species descriptions. Spore wall characteristics were examined at $\times 1000$ magnification using stains and Melzer's reagent. Spellings of scientific names of mycorrhizal species are those suggested by Almeida¹⁵. Seven spore-forming AM fungi, *Acaulospora scrobiculata* Trappe, *Glomus geosporum* (Nicol. & Gerd.) Walker, *Glomus aggregatum* Schenck & Smith emend. Koske, *Glomus micr aggregatum* Koske, Gemma & Olexia, *Scutellospora calospora* (Nicol. & Gerd.) Walker & Sanders, and undescribed species of *Acaulospora* (AY) and *Gigaspora* (GiB) were present in the rhizosphere of different tree species (Table 1).

Forty grams of soil inoculum, containing resting spores, infected root fragments and mycelia was placed about 6 cm below the soil surface in each mycorrhizal pot. Thirty-day-old uniform seedlings of *C. siamea* and *D. indica* were planted in mycorrhizal and non-mycorrhizal pots at the rate of one seedling per pot. For each host species, there were five treatments and each treatment was replicated three times. Pots were kept in the greenhouse in a randomized block design and watered daily as necessary. The temperature during the experiment ranged from 20 to 35°C and the photoperiod was 13 h.

Seedlings were harvested 180 days after transplanting. Dry weight of shoot and root was determined after drying samples at 70°C for 96 h. Phosphorus content was determined after digesting dried plant parts in tri-acid mixture containing $\text{HNO}_3 : \text{H}_2\text{SO}_4 : \text{HClO}_4$ (10 : 1 : 3) and analysing by molybdo-phosphate method¹⁶. Roots were examined at $\times 100$ –400 magnifications for the presence of infection after clearing with 10% KOH, acidifying in dil.HCl and staining in 0.01% acid fuchsin in lacto-

phenol¹⁷. Darkly pigmented roots were immersed in an alkaline solution of H_2O_2 until bleached¹⁸. Fifty 1 cm root segments, randomly collected from each plant species, were scored for the presence or absence of infection using slide method for assessing percentage mycorrhizal infection¹⁹. Spores were identified to species and counted by the method described above. Data were analysed using one-way analysis of variance.

Shoot and root dry weight and tissue P concentration in *C. siamea* plants were significantly increased in mycorrhizal pots inoculated with soils from under *D. sissoo*, *C. siamea*, *D. indica* and *A. indica* relative to uninoculated control. Plants inoculated with *E. hybrid* soils showed no significant difference in shoot and root dry weight and tissue P concentration relative to uninoculated control. Among mycorrhizal treatments, significantly higher shoot and root dry weight and shoot P uptake was observed in pots inoculated with *D. indica* soils. Arbuscular mycorrhizal infection was significantly higher in plants inoculated with the rhizosphere soils of *D. indica* (Table 3). Spores of *S. calospora* were present in pots inoculated with *C. siamea* and *D. indica* soils. Maximum number of spores (27) was observed in the pots inoculated with rhizosphere soils of *D. sissoo*. Lowest percentage of mycorrhizal infection (48) was observed in pots inoculated with *E. hybrid* soils.

Mycorrhizal inoculation with rhizosphere soils of *D. sissoo*, *C. siamea*, *D. indica* and *A. indica* significantly improved shoot and root dry weight and tissue P concentration of *D. indica* over uninoculated control. Shoot and root dry weight and tissue P concentration in plants inoculated with *E. hybrid* soils showed no significant difference relative to control. Among mycorrhizal treatments, significantly higher increase in root dry weight and shoot and root P concentration was observed in pots inoculated with *A. indica* soils. There was no significant difference in per cent mycorrhizal infection in plants inoculated with soil inoculum from under *D. sissoo*, *C. siamea*, *D. indica* and *A. indica* (Table 5). Maximum number of total spores (100) was observed in pots inoculated with the rhizosphere soils of *D. sissoo*. Lowest mycorrhizal infection (67.6%) and total

spore population (6) were observed in pots inoculated with soil inoculum from under *E. hybrid*.

In general, rhizosphere soils of *D. sissoo*, *C. siamea*, *D. indica* and *A. indica* tested as AM inoculants on *C. siamea* and *D. indica* produced more than 40% increase in shoot dry matter production over uninoculated control. There was no relationship between per cent mycorrhizal infection and spore numbers. Spores or sporocarp of mycorrhizal species, *G. aggregatum*, *G. micraggregatum*, *Acaulospora* sp. (AY) and *Gigaspora* sp. (GiB) present in rhizosphere soils of different host species from revegetated mine spoil were not observed in mycorrhizal pots.

The study shows that whilst rhizosphere soils of *D. sissoo*, *C. siamea*, *D. indica* and *A. indica* acted as an effective source of arbuscular mycorrhizal inoculum, soils taken from under *E. hybrid* were not effective in enhancing plant growth. The AM fungal species, *A. scrobiculata*, not only effectively colonized root but also consistently increased P uptake and shoot dry matter production in both *C. siamea* and *D. indica*. Studies on competitive interactions between arbuscular mycorrhizal species have suggested that the fungal species that colonize root first, may be at an advantage over late colonizers²⁰. This may account for the widespread occurrence of *A. scrobiculata* in revegetated coal mine spoil, as is evident by its presence in the rhizosphere soils of all the tree species, except in *E. hybrid*. Significantly higher increase in growth and P uptake in *C. siamea* inoculated with *D. indica* soils was an effect

of higher root colonization due to the presence of both *A. scrobiculata* and *S. calospora*, as was evident by the presence of spores of the two mycorrhizal species in pots. Previous studies have also revealed that inoculations with mixed inoculum, containing more than one AM endophyte, resulted in higher root colonization and increased P uptake and growth in plants^{7,21,22}. Recently, increased growth in plants inoculated with dual inocula of AM fungi has been reported to be due to the increased transfer of P to the shoot from the root⁷. No significant change in shoot biomass and P uptake in plants inoculated with *E. hybrid* soils, relative to uninoculated control, was possible due to the constant balance maintained in carbon or P demand between the source (host) and the sink (fungus). *G. geosporum* associated with plants inoculated with *E. hybrid* soils was not effective in increasing P uptake and shoot biomass.

From this study, it is evident that whilst *C. siamea* support growth and reproduction of both *A. scrobiculata* and *S. calospora*, *D. indica* favours growth of *A. scrobiculata* only. This supports the works showing that host plants can be selective in the growth and reproduction of certain AM fungal species under a particular set of environmental conditions^{22,24}. Apparent host specificity may, however, occur if host susceptibility does not coincide with the propagule infectivity⁵. Spores of *S. calospora* were not present in *D. indica* soils used as inoculum, but were formed in mycorrhizal pots of *C. siamea* inoculated with the same soil. This indicates

Table 2. Dry weight and phosphorus concentration of *Cassia siamea* inoculated with soil inoculum from under five tree species

that *S. calospora* also persisted in the form of propagules other than resting spores. Previous studies have shown that the network of intra- and extra-radical hyphae or intra-radical spores act as important sources of AM propagules in dry soils^{12,20,25}. The variable amount of mycorrhizal spores present in the soils used as inoculum source had little effect on the percentage infection of roots at the final harvest. Gazey *et al.*²⁶ also found that the amount of *A. laevis* inoculum added had little effect on the proportion of roots colonized, once maximum percentage of root length colonization was reached. Therefore, it appears that the increasing number of infections with increasing inoculum density usually results from an increasing probability of infection by individual propagules of mycorrhizal species, rather than from increased energy. Maximum number of spores of *A. scrobiculata* were consistently produced in pots inoculated with rhizosphere soils of *D. sissoo*, which incidentally had the highest amount of spore inoculum. This supports the work of Gazey *et al.*²⁶ who also found that the number of spores produced in *A. laevis* differs with the inoculum quantity. Since the root system of *C. siamea* is relatively coarse with fewer root hairs than *D. indica*, it is plausible that a comparatively lower population of *A. scrobiculata* in *C. siamea* pots relative to *D. indica* pots was due to the differences in the root morphology²⁷.

Unsterilized coal mine soil was used as a substrate in the present investigation, as it provided 'natural

conditions' for the growth of ecologically adapted strains of AM fungi. Evidence of ecological adaptation in mycorrhizal fungi has been provided by several workers^{3,28}. The results of this study justify the use of revegetated coal mine spoil as an effective and economical source of endomycorrhizal inoculum from within the production system, but suggest the need to evaluate the specific effects of rhizosphere soils from revegetated overburden as sources of AM inoculum on individual host species prior to their utilization in large-scale nursery inoculations.

INSA MEDAL FOR YOUNG SCIENTISTS – 1997

Instituted by the Indian National Science Academy in 1974 the Medal is awarded annually in recognition of outstanding work of scientists below the age of 32. Only those born on or after 1 January 1965 are eligible for consideration in 1997. The work done in India by the nominee will only be taken into consideration for the award.

The awardee is presented a medal, a certificate, and a cash award of Rs. 25,000. In addition, the recipient may be considered for a research grant up to Rs 5 lakhs for a period of three years. Preferential consideration will also be given for attending conferences/pursuing collaborative research under bilateral exchange programme with overseas Academies. An awardee, who is unable to obtain a suitable placement, will be considered for an interim Fellowship.

A candidate may only be nominated once. However, a nomination will remain valid for consideration for 3 years or until the age of eligibility whichever expires earlier.

Nominations for the awards for 1997 may be made by Fellows of the Academy, previous recipients of INSA Medal for Young Scientists as also by the established scientific societies of all India character, University faculties and departments or the research institutions. Last date for the receipt of nominations in the Academy is 15 November 1996.

Nomination proforma can be obtained from Dr Alok Moitra, AES (Council), Indian National Science Academy, Bahadur Shah Zafar Marg, New Delhi 110 002 by sending a self-addressed envelope of 25 cm × 12 cm size.

BOOK REVIEWS

The Collected Papers of Albert Einstein: Volume 1 – The Early Years, 1879–1902; Volume 2 – The Swiss Years: Writings 1900–1909; Volume 3 – The Swiss Years: Writings, 1909–1911. English Translation. Princeton University Press, Princeton, New Jersey – a combined review.

When Albert Einstein died in April 1955 at the age of seventy-six, his estate passed into the joint custody of his long-time secretary Helen Dukas, and his close friend Otto Nathan who was named sole executor. Making Einstein's writings and papers – especially his collected scientific works – widely available to the community of scholars has taken an inordinately long time, not merely because of the volume of material involved. Under the joint sponsorship of the Hebrew University of Jerusalem, where the Einstein Archive of 43,000 documents is housed, and Princeton University Press, and with John Stachel of Boston University as overall Editor, a monumental series of about forty volumes – the Documentary Edition – started appearing in the late eighties. Simultaneously, under a separate project supported by the National Science Foundation of the USA, Princeton University Press is making available a companion series of volumes containing English translations of the original volumes, specially prepared by Anna Beck with the assistance of Peter Havas and Don Howard. Some volumes in the series contain general correspondence during the various phases of Einstein's life, while the others contain his scientific papers in the same periods. The present review looks at volumes 1, 2 and 3 of this latter project, while a review of the later volume 5 has appeared earlier in *Current Science* (1995, 69, 882).

The prefaces to these volumes clearly state that they do not stand on their own, but must be taken as supplementing the more comprehensive Documentary Edition which contains material in the original languages, with numerous footnotes and explanations, which are here omitted. This robs these volumes of their value only slightly, though one misses some of the presumably illuminating cross-references and editorial comments.

Volume 1 is devoted to correspondence during the years 1879 to 1902 – from Einstein's birth to age twenty-three. More

than half the letters included here were apparently discovered by the editors while preparing this volume, and this includes over fifty letters between Einstein and his fellow student and first wife Mileva Maric. The volume begins with an extract from a biographical sketch of Einstein by his younger sister (and only sibling) Maja, written with sisterly affection. It covers the history of the family over a couple of generations, and the ill-starred business adventures of the father Hermann Einstein who ultimately died early really unaware of his son's extraordinary powers. Maja sees her mother Pauline nee Koch with understandable fondness, and talks of the qualities of perseverance, concentration and love of music evident in Albert already at a young age. 'Only persistence that does not rest until all that is unclear is eliminated and all difficulties are overcome allows an idea to take shape and be recognized as truly one of genius.' He was given to violent tantrums as a young child but these soon disappeared. Maja credits Pauline for Albert's affinity for music, and Hermann for his love of logical thinking and mathematics. After the parents' move to Italy in 1894, in search of better fortunes, Albert became acutely unhappy with the rigid curriculum at the Luitpold Gymnasium in Munich – we remember that a generation later a similar school produced Werner Heisenberg! Young Albert ran away from school to Italy, then spent a year at a more congenial cantonal school in Aarau in Switzerland, and vowed to make it on his own to study at the prestigious Federal Institute of Technology – ETH – in Zurich. In this he was supported by his parents. This excerpt ends in 1896, about the time Albert was ready to enter the ETH as a student of mathematics.

From the rest of volume 1, we get already a clear picture of what was to come: his great admiration for the writings of Kirchhoff, Helmholtz and specially Boltzmann; and his early thoughts and preoccupation with problems of electrodynamics of moving bodies, the problem of the ether, with the Planck radiation law and the photo effect of Lenard, the foundations of thermodynamics, and molecular motions and sizes. There are also grade sheets from various exams, and the lengthy encounter with the Swiss bureaucracy in connection with his application in 1899 for Swiss citizenship granted in

1901. Good to see that these wheels grind slowly always and everywhere! There is a touching letter from Einstein's father to his teacher and guardian Jost Winteler at whose home he stayed while in Aarau: 'It is a great relief to know that my son is under such loving care which is not only concerned with his physical well-being but also promotes his intellectual and inner life in such a noble fashion. At this young age the heart is most receptive to a good model and I am convinced that your good influence will leave a lasting effect.' A brief – almost inevitable – adolescent affair with the Winteler daughter Marie ended by 1897. Then begins the exchange of letters with Mileva Maric, his fellow student at the ETH during 1896–1900. Gradually one sees the intensity of feelings grow and find expression. What does strike one is his generally optimistic and sunny disposition even in the most adverse circumstances, while she tends to be introverted and given to moods of depression and apprehension on various counts. Also there are remarkably few letters from Mileva to Albert – perhaps irretrievably lost?

At the ETH the mathematician Hermann Minkowski taught Einstein no less than nine courses over the four-year period. He also attended a course on Kantian philosophy. Detailed class notes on a 1897–98 physics course by Weber are included. While figures are unfortunately missing, it is interesting to see what such a course encompassed a century ago – heat flow and thermal conductivity, the nature of heat, Carnot's theorem and the Second Law; and some material on static and current electricity, with a good deal of experimental detail to accompany the theory.

An early 1898 letter from Albert to Maja recalls their parents' sad state and his inability to help them materially. Then already in 1899 in a key letter to Mileva he says the ether is problematic and that electromagnetic waves propagate in empty space with no carrier: 'I am more and more convinced that the electrodynamics of moving bodies, as presented today, is not correct, and that it should be possible to present it in a simpler way. I think that the electric forces can be directly defined only for empty space, (which is) also emphasized by Hertz.' The initial friendly but formal letters to Mileva turn more warm and intimate; but at the same

time there are references to family tensions and his parents' profound unhappiness at this friendship. Now and then we see expressed Albert's feelings of frustration and happiness denied, but a faith that the future will make amends: 'But destiny seems to bear some grudge against the two of us. But this will make things all the more beautiful later on, when all obstacles and worries have been overcome.' The earliest reference to his interest in the photo effect and Lenard's experiments is in a May 1901 letter, about the same time he expresses his being not fully convinced by Planck's work on radiation. On the employment front, there were many enquiries but few opportunities, and for a while Albert and Mileva lived a hand-to-mouth existence with temporary 'leave vacancy' teaching positions. Despite all these difficulties his intense commitment to scientific problems and independence of thought are always evident. The offer of the post of 'Technical Expert Class 3' at the Patent Office in Bern in June 1902 – with the timely help of a good friend – finally brings freedom from financial worry, and the chance to devote himself 'in his spare time' to his true interests.

Turning next to volumes 2 and 3, these contain Einstein's scientific writings during the periods 1900–1909 and 1909–1911 respectively. From 1902 to 1909 he worked at the Patent Office, then from 1909 to 1911 as an Associate Professor at the University of Zurich. There was then a brief move to Prague, followed by a return to Zurich as a professor at the ETH. This did not last long, as in early 1914 he made the move to the Prussian Academy of Sciences at Berlin. Thus ended his Swiss period. Towards the end of volume 3 there are some papers written from Prague. In spite of the declared shortcomings of these volumes they are an unbelievable treasure for every serious student of physics.

The earliest papers in volume 2 deal with problems of capillarity, intermolecular forces and ways of parametrizing them. Then appear three fundamental papers on statistical mechanics, which are however not very well known. The first of these was submitted in June 1902, evidently exactly one week after receipt of the letter of appointment at the Patent Office. In this paper Einstein declares that his aim is to close the gap, in the foundations of thermodynamics, between mechanics

and probability, and arrive at the laws of entropy, thermal equilibrium and the Second Law. These were his own independent approaches to these very basic problems; while he was deeply influenced by Boltzmann's work (in many letters to Mileva he asks for 'my copy of Boltzmann'), it turned out that Gibbs' work was not available to him. Indeed in a short note of 1910 reproduced in volume 3, Einstein remarks: 'Had I been familiar with Gibbs' book at that time, I would not have published those papers at all, but would have limited myself to the discussion of just a few points.' These papers are written in a not too transparent style – compared of course to his later masterpieces. But without doubt careful study of each of them, even almost a century later, would be most rewarding.

Now we come to the magic year 1905. So often have we been told, and so often have we told others, that this was a year of miracles for physics. In volume 2 we see why, and using the colloquial expression any decent physicist would gladly give an arm and a leg to have translations of the trio of 1905 papers next to her pillow – the 'photon paper' submitted on March 17th, the Brownian Motion paper submitted on May 11th, and the Special Relativity paper sent in at the end of June. The thrill of reading the originals, even in translation, is indescribable. In each of these papers we find a vastly improved writing style (compared to 1902), and complete mastery of ideas and understanding. Already in the first paper deriving the existence of quanta of radiation from the Wien limit of Planck's radiation law, Einstein speaks of localization and indivisibility of quanta – '... when a light ray is spreading from a point, the energy is not distributed continuously over ever-increasing spaces, but consists of a finite number of energy quanta that are localized in points in space, move without dividing, and can be absorbed or generated only as a whole'. The application to explain the Lenard photo effect comes towards the end. The Brownian motion paper is designed to present convincing evidence for the reality of molecules and estimating their sizes. A few years later, in 1908, he presented a simpler account specially for chemists (Document 50 of volume 2). In between, his Ph.D. thesis submitted to the University of Zurich – again in 1905, dedicated to his close friend Marcel Grossmann, titled

'A new determination of molecular dimensions', and just eighteen pages long – is reproduced in its entirety.

The special relativity paper is the last of the three great works of 1905, and also the longest. The two postulates are stated boldly at the very outset, and it is stunning to see the majesty of the arguments unveiling the inevitable consequences. The analysis of time and the problem of simultaneity, the insistence on clearly given operational procedures for measurements, are as fresh to read today as ninety years ago. The first part deals extensively with space-time kinematics, the Lorentz transformation laws and their consequences, and even the twin paradox. He then proceeds to the application to the electrodynamic equations of Maxwell and Hertz, the Doppler effect, aberration, etc. The level and comprehensiveness of the exposition – in this very first paper – is unbelievable. Yet many years later Einstein would say that this work on special relativity was no comparison at all to the struggles he faced both with quantum theory and general relativity.

Many later papers come back to one or another point raised by these landmark works. The mass energy equivalence is given in a September 1905 paper. Volume 2 contains also a multitude of reviews of papers by others. Among his own master works we find here the 1906 paper applying the Planck idea to the problem of specific heats; and the December 1907 Jahrbuch review of special relativity towards the end of which he hints at the problem of gravitation. This fine sentence on the dispensability of the ether is well worth recall: '... electromagnetic forces appear here not as states of some substance, but rather as independently existing things that are similar to ponderable matter and share with it the feature of inertia'. We also remember that the Principle of Equivalence – 'the happiest thought of my life' – which formed the cornerstone of general relativity, came to Einstein while he was composing this review.

The final jewel in this volume is the text of the 1909 Salzburg Lecture wherein he analysed the energy fluctuation formula based on Planck's Law, and from this was led to the wave-particle duality for radiation – 'All I wanted is briefly to indicate... that the two structural properties (the undulatory structure and the

quantum structure) simultaneously displayed by radiation according to the Planck formula should not be considered as mutually incompatible.'

Volume 3 is somewhat different in character and content from volume 2. It covers the period 1909 to 1911 throughout which Einstein was at the University of Zurich. The major part of this volume is devoted to the lecture notes he prepared for three of his courses – mechanics taught during winter 1909–1910; kinetic theory of heat taught during summer 1910; and electromagnetism taught during winter 1910–1911. Elsewhere (in volume 5) Einstein writes that he enjoyed teaching a great deal. These lecture notes tend to be telegraphic and fragmentary, not in the style of his beautiful papers; yet they are valuable to see the organization of his thoughts and the way he conveyed them to students. Of the three sets of notes, the one on mechanics is relatively complete and coherent; while that on the kinetic theory of heat tends to be sketchy. Einstein goes to some effort to stress the nontrivial content of the principle of virtual work and d'Alembert's principle in dynamics, and many down-to-earth problems of mechanics are presented including rigid body kinematics and rotational motion. While the standard conservation laws are covered, the link to symmetry is not yet seen! The kinetic theory course emphasizes that molecular theoretic foundations can lead to all the basic statistical results for macroscopic systems. In the notes on electricity and magnetism, we see a sophistication in style and level of ideas, including this statement of the conception of a theoretical scheme as a totality and how it should be judged: 'We set up a conceptual system the individual parts of which do not correspond directly to empirical facts. Only a certain totality of theoretical material corresponds again to a certain totality of experimental facts.' These notes are also fairly well-organized, and have a practical feel about them. They go up to the Maxwell equations, but stop short of discussing the vector potential, the Lienard-Wiechert solutions, the gauge transformation idea, or a covariant formulation.

Aside from these three major items in this volume, there is a superlative 1910 review of special relativity, giving the historical origin of the ether concept, its problems, its demise, and then going on to his own work. A later 1911 Zurich

lecture is equally superb, but this time highlighting the role of Galilean invariance in mechanics and the need to retain it in electrodynamics. In the discussion that follows the lecture, Einstein handles all the searching questions with complete confidence, and at the end points out that special relativity is a restrictive concept and not a specific model for any phenomenon: 'The principle of relativity is a principle that narrows the possibilities; it is not a model, just as the second law of thermodynamics is not a model.' Some papers go back to the ideas of the 1905 'photon' paper and pose questions which at that time were of the greatest import: are quanta intrinsic to radiation or are they only linked to matter? Inter alia he refers to his 1905 calculations, and says in effect, 'I have shown that the Maxwell field on its own "must be quantized"'. What bold declarations and deep insights into phenomena, and of the directions in which future progress would have to go! In so many of his papers we see his grasp and mastery of statistical concepts – the manifold and often startling uses of the Boltzmann connection $S = k \ln W$, the exploitation of fluctuations – to tease out the implications of experimental observations, the limitations of theory. We see the power of his arguments from first principles, an uncanny gift for seeing far in advance of others the need for fundamental conceptual advances in so many directions. He had the ability not only to lead but to point to others the most promising directions.

Towards the end of volume 3 are two papers written – one suspects in a leisurely style – from Prague, one on molecular motions in solids and another on his first insights into the influence of gravity on light. Another major document is the extended 1911 Solvay Congress lecture on the specific heat problem. Here again Einstein expresses his conviction that the foundations of both mechanics and electrodynamics would have to be profoundly altered to take account of the quantum; it is staggering to read these lines from one who had done so much for the understanding of space and time. And the 'paradox' of wave particle duality for radiation is expressed again.

The declared limitations notwithstanding, every professional physicist will find these volumes (and surely the succeeding ones) of abiding value and interest. To

see how fundamental theories took shape and came into being, to perceive what led to them, to be face to face with documents which heralded the birth of many conceptions taken today for granted, to see that there was a time when they did not exist, and to view them condensing out of a mist and take on permanence after creation in Einstein's mind – these are experiences beyond value.

Wild Edible Plants of India: Diversity, Conservation and Use. R. K. Arora and Anjula Pandey. National Bureau of Plant Genetic Resources, New Delhi. Price not stated.

From an initial phase of hunting and gathering to agricultural societies and finally to industrial economic societies, there has been progressive decline in the number of species on which human race has depended for food and other needs. In this process, while the biodiversity base became progressively smaller, bioproductivity per unit area and time increased dramatically. The chief reason was application of principles of genetics and plant/animal breeding. This resulted in the release of time for vocations other than growing food, and also led to increase in population in some parts of the world. However, there is now a realization that to make agriculture sustainable, wide genetic diversity base has to be combined with high bioproductivity. This is a major challenge before agricultural scientists and technologists.

Judging against this background, the book is both very timely and most welcome. This book is the sum total of life-long work of R. K. Arora on India's agri-biodiversity, its ancestors and the related species. Arora's special strength has been that he combines knowledge and experience of a professional botanist, ecologist and geneticist, all rolled into one. The authors, and NBPGR and ICAR deserve hearty congratulations for this

excellent and most unique work. In this venture Arora has been admirably assisted by Anjula Pandey. On all counts women, by their very nature and intuitively have been far more committed conservationists than men. In fact women as gatherers have played a very crucial role in domestication of crops/animals in the world at four nuclear centres of agricultural development in the Fertile Crescent, Southern Mexico, Andes and Huang Ho in China.

The book is a successor to an earlier book entitled *Wild Edible Plants of India* (1978) published jointly by the late H. B. Singh and R. K. Arora which was essentially a floristic enumeration of species diversity used for various plant parts. The present authors have not only vastly updated the earlier information base, but also added several altogether new and relevant material.

Part I of the book deals with the diversity of species, which have been enumerated on the basis of the useful plant parts namely, underground parts, leaves and shoots, buds and flowers, fruits, nuts and seeds. Species in each category have been listed alphabetically using their botanical name together with common names as far as possible. An account of each species includes its distributional range together with its use and floristic and ethnobotanical information of the edible plant part used. Wherever possible, information on actual nutritive value has also been provided. The authors have also included very valuable ethnobotanical information regarding the use by local communities. This use has been

based on trial and error experiments carried over the years supplemented by conscious selection made by the communities. The results of such large scale trials are today available to the present generation free of cost. Regrettably such efforts are neither regarded as innovation nor are they patentable or awarded/rewarded.

The number of species included in this book is around 1000. These also include, foods used by local people (including the ecosystem people) in times of famine and excessive droughts in order to subsist in such conditions. In addition, over 150 wild edible lower plants (e.g. algae, fungi, lichens, pteridophytes and gymnosperms) have also been included.

Part II of the book deals with wild and domesticated diversity together with plants with future potential. In that sense, these are rather less known economic plants that have a potential to come into the mainstream of agriculture. Over 56 species have been listed and many of these species have definite potential for being used on a large scale. The broad categories are: roots and tubers, leaves, vegetable, flowers and buds, tropical-subtropical fruits, temperate fruits and seeds/nuts/kernels. This category also contains many unconventional plants. Most of these are already in use and have potential to be cultivated on a large scale. Special mention may be made of bamboos which have tremendous potential as a source of raw material for paper pulp and furniture industry and as building material.

Part III of the book is devoted to conservation concerns, involving both *in*

situ and *ex situ* approaches. In addition, technology for cultivation of some of the important species needs to be developed so as to lessen the demand from the natural populations and thus help in their conservation. Some incipient domesticates are with tribals and other ecosystem people. More often, these are treasure troves of useful genes. All these need to be brought under a conservation plan because the concerned people may no longer cultivate these for long and they may abandon them for more productive varieties.

This is an excellent book and contains wealth of information in a consolidated form. With this as the base, there is need to build up a data base. Equally important is to take a total view of and plan for long term *in situ* and *ex situ* conservation of these species. The various user Departments/Ministries in Government of India and concerned States in India need to evolve a National Action Plan with a long-term perspective. I have no doubt this book would be extensively used by professional botanists, breeders, biotechnologists, experimental evolutionists as well as grass-root workers. It is indeed a trend-setting work which needs to be followed by all biodiversity-rich developing countries in tropics and sub-tropics. The authors deserve hearty congratulations for this exemplary work.

NATIONAL METALLURGICAL LABORATORY
(Council of Scientific & Industrial Research)
Jamshedpur 831 007

Advertisement No. 2/96

National Metallurgical Laboratory (NML) is a constituent of the Council of Scientific & Industrial Research which is a premier body established to undertake Scientific & Industrial Research. NML is a leading R&D Organization engaged in a spectrum of time bound projects of industrial importance and active research relating to mineral beneficiation, extraction of metals and their processing, environmental engineering, refractories, engineered materials developments, chemical analysis, corrosion protection and failure analysis of engineering components. The Laboratory has excellent infrastructure like information and computer services besides sophisticated instruments for carrying out advanced research. It provides very good opportunities for career growth of its employees. The Laboratory has regional centres at Ahmedabad, Batala, Calcutta, Digha and Madras to cater to the local needs.

The Laboratory intends to fill up several vacancies available at different levels with young intelligent and dynamic personnel willing to take up challenging jobs.

The following positions are available:

1. SCIENTIST GR.IV(2): 5 Posts (General)

Scale of pay: Rs 3000-100-3500-125-4500

Age: Not exceeding 35 years

Qualification and experience

Essential: 1st class M Sc (Chemistry/Physics/Industrial Chemistry/Materials Science/Geology) with not less than 65% marks or 1st class B E /B Tech or equivalent with not less than 65% marks and 4 years experience or M Tech (Chemical Engineering/Material Science /Mechanical/Metallurgy) with 2 years experience or Ph D (Engineering/Science) with one year experience.

Desirable: Proven experience of 4 years in the area of foundry, mechanical working, materials synthesis/material characterization, extraction of metals and corrosion protection and prevention.

Job description: The incumbents will lead/assist a team of scientists/technologists in different areas relating to special materials development, materials evaluation, non-destructive testing, refractories, iron and steel, etc.

2. SCIENTIST GR.IV(1): 20 Posts (SC-3, ST-3, OBC-4, Gen.-10)

Scale of pay: Rs 2200-75-2800-EB-100-4000)

Age: Not exceeding 35 years (40 years for SC/ST, 38 for OBC)

Qualification and experience

Essential: 1st class M Sc (Physics/Chemistry/Industrial Chemistry/Materials Science/Geology) or 1st

class B E or B Tech in Metallurgy/Chemical Engineering/Computer applications/Geology with not less than 65% marks or M E/M Tech in Materials Science/Metallurgy.

Desirable: Proven experience of about 2 years in the relevant disciplines like alloy development, physical characterization, microstructural analysis, mechanical testing, failure analysis, structural integrity analysis, non-destructive testing, foundry, environmental monitoring, mineral beneficiation, pyro and hydrometallurgy, refractories and ferrous process metallurgy, organometallic chemistry, systems analysis, information sciences, with high skill in operation and maintenance of sophisticated equipments for mechanical testing, X-ray and electron metallography, non-destructive testing, dilatometry, potentiometry spectroscopy, etc.

Job description: The incumbents will assist a team of scientists/technologists in various projects relating to one or more of the following: Mineral processing, extractive metallurgy, refractories, mechanical testing, materials characterization and processing, data processing. The job may require visits to industrial plant sites.

3. TECHNICAL OFFICER GR.III(4): 2 Posts (for OBC)

Scale of pay: Rs 2200-75-2800-EB-100-4000

Age: Not exceeding 38 years

Qualification and experience

Essential: 1st class B Sc (Physics/Chemistry/Mathematics) with 8 years experience or M Sc (Physics/Mathematics/Electronics) or B E/ B Tech or equivalent qualification with 55% marks and 6 years experience.

Desirable: Proven experience of about 2 years in the maintenance of all kinds of electronic equipments, computers, electronic data processing, etc. with a bent of mind to look into trouble shooting problems, signal analysis. The job may also require visits to industrial plants for on the spot studies.

Job description: To assist in maintenance of equipment, electronic data processing.

4. TECHNICAL ASSISTANTS GR.III(1): 2 Posts (1 SC, 1 General)

Scale of pay: Rs 1400-40-1800-EB-50-2300

Age: Not exceeding 28 years. For SC 33 years

Qualification and experience

Essential: B Sc (Physics/Chemistry/Mathematics)/ 1st class diploma in Instrumentation/Computer Applications.

Desirable: Experience of about 2 years in electronic data processing, metallography, maintenance of electronic equipments, computers, etc. with a bent of mind to solve operational problems in these equipments.

Job description: Maintenance of sophisticated electronic microprocessor based instruments of the laboratory like the creep testing equipments, electron microscopes, physical and structural characterization equipments, analytical equipments, etc.

5. MEDICAL OFFICER GR.III(4): 1 post (General)

Scale of pay: Rs 2200-75-2800-EB-100-4000

Age: Not exceeding 35 years

Qualification and experience

Essential: 1st class MBBS or equivalent.

Desirable: Experience of about 2 years preferably in hospitals/dispensaries attached to industrial units.

Job description: The incumbent will render medical assistance to the staff and members of their families, be willing to work in the first aid/dispensaries located in the residential colonies and assist the Senior Medical Officer in improving the medical facilities.

GENERAL CONDITIONS

1. The number of posts advertised is only indicative.
2. Prescribed application forms may be obtained from the office of the Sr. Controller of Administration, National Metallurgical Laboratory, Jamshedpur 831 007 up to 22 July 1996 by sending a self-addressed stamped envelope (26 cm x 11 cm size) bearing postage stamp of Rs 2. Name of post may please be mentioned on the top of the envelope.
3. The application completed in all respects along with a recent passport size photograph pasted on the right hand corner on the top of the application, along with a crossed Demand Draft for Rs 25 drawn in favour of Director, National Metallurgical Laboratory, should reach the Director, NML, Jamshedpur, by 14 August 1996. Candidates applying for more posts than one should submit separate application along with prescribed application fee, etc.
4. Scheduled Caste/Scheduled Tribe candidates and departmental candidates of CSIR and its Lab./Inst. are exempted from the payment of application fees.
5. The maximum age prescribed shall be reckoned as on 14-08-96.
6. Appointment of Scientists will be on contract for a period of 6 (six) years in the first instance except for CSIR employees already declared permanent in lower posts. Contract is extendable upon satisfactory performance.
7. Applications from candidates working in Government Departments, Public Sector Undertakings and Autonomous Organizations will be considered only if forwarded through proper channel and with a no objection certificate that the applicant will be relieved within one month of receipt of the appointment order.
8. Mere fulfilling the minimum advertised requirements does not automatically entitle an applicant to be called for interview. The decisions of the screening committee will be final and binding in this matter.
9. Candidates called for interview/test will be paid 2nd class TA by the shortest route between Jamshedpur (Tatanagar railway station) and the actual place of journey or the place of address of correspondence mentioned in the application whichever is nearer.
10. Higher start of pay may be considered in case of exceptionally meritorious candidates.
11. The relaxation in age limit, qualification and/or experience may be allowed only in exceptionally meritorious candidates, with the prior approval of the competent authority.
12. Besides Head Quarters at Jamshedpur, candidates appointed may be posted anywhere in the NML field stations located at Ahmedabad, Batala, Howrah/Calcutta, Digha, Madras.
13. Applications incomplete in any respect or received after the due date are liable to be rejected.
14. In all matters relating to this advertisement and subsequent processing, the decision of the Director, National Metallurgical Laboratory, Jamshedpur will be final and binding.
15. Canvassing in any form and/or bringing in any influence, political or otherwise, will be treated as disqualification for the post.
16. Interim inquiries will not be attended to.
17. All the posts carry usual allowances as admissible under the Central Govt Rules. Apart from that the post of Medical Officer carries a non-practising allowance of Rs 600/- per month.

INDIAN COUNCIL OF AGRICULTURAL RESEARCH
Jawaharlal Nehru Awards for Post-Graduate
Agricultural Research—1996

The Indian Council of Agricultural Research invites applications from post-graduate students who have obtained their Ph D degrees during the year 1995 in India in Agriculture or Allied Sciences for Jawaharlal Nehru Awards for Post-graduate Agricultural Research—1996. There will be sixteen prizes of Rs 10,000 each for outstanding research work of the following nature:

- (i) which may have bearing on finding a solution to any important national problem in the field of agriculture/ animal sciences, and/or
- (ii) which is likely to have impact on increasing the production or improving the quality of any important crop, human nutrition or animal productivity or increasing the technological efficiency of any process of economic importance connected with agriculture.

Candidates shall be required to submit the following document along with application form through the head of the Institute from where the thesis has been obtained.

- (i) A copy of the Ph D degree certificate.
- (ii) A copy of the thesis submitted by them for the award of doctoral degree.
- (iii) A certificate from the guide of the candidate for Ph D degree stating the extent to which the work is the candidate's own contribution.
- (iv) Six copies of the synopsis indicating precisely and in concise terms the work done by the candidate.
- (v) Any reprint of papers published/presented based on the doctoral thesis.
- (vi) Six copies of the application form with complete address for correspondence with telegraphic address if possible.

Each candidate will be judged on the basis of the originality and the applied value of the investigations as revealed in the thesis submitted by him. In all matters relating to the award, the decision of the Council shall be final and no correspondence on this account will be entertained. The candidates who obtained their Ph Ds in 1995 only need apply. The prescribed proforma for applying for this award may be obtained from the Council on or before September 15, 1996.

Application with complete documents as mentioned above, addressed to Dr R. C. Maheshwari, Assistant Director-General (CSC), ICAR, New Delhi 110 001, should be sent so as to reach on or before October 15, 1996. The last date for candidates in the Andaman and Nicobar Islands, Lakshadweep, States/Union Territory in the North Eastern Region, Ladakh Division of J & K State and Sikkim is October 31, 1996. The award-winning thesis will be retained by the Council for record. In case the application is not accompanied by a copy of thesis and the required number of copies of synopsis, the application form is liable to be rejected at the screening stage.

Controlling gene expression

The control of gene expression is primarily at the level of transcription, the step where information stored in the sequence of bases in DNA is transcribed into messenger RNA. The regulation of genes is then predominantly effected by the binding of specific proteins to control elements in the non-coding stretches of DNA.

Protein-DNA interactions are the molecular switches that modulate gene expression. Much of our present day understanding of gene expression dates back to the path-breaking work of Jacob and Monod, which led to the operon model. Several decades later the structures of protein repressors, the operator DNA segments and sometimes their complexes are available as a consequence of NMR or crystallographic studies. This wealth of molecular information promises to reveal the functioning of these regulatory switches at near-atomic resolution. Siddhartha Roy (page 100) describes biophysical studies on an important regulatory protein, the λ -repressor, which is crucial in switching the bacteriophage λ from the lysogenic to lytic mode of growth. Transcriptional control of gene expression is an area where the fusion of molecular genetics and structural biology has had a major impact.

High energy physics

At the November 1995 meeting of the Indian Academy of Sciences, held in Madras, a special session was hosted by the Indira Gandhi Centre for Atomic Research, Kalpakkam. This was devoted to the

topic of 'High Energy Physics in the 21st Century'. This issue contains a special section (page 109) with written versions of many of the talks given, as it was felt by many that the theme and content would be appreciated by a wider audience.

The special section opens with G. Rajasekaran's overview, which itself introduces the articles that follow. It also states the basic driving force for high energy physics research. In spite of tremendous progress from the beginning of this century, our current basic idea of space and time is that given by Einstein and the quantum theory we use today is just a descendant of Planck's creation. But surely these ideas must give way to new ones as we probe shorter scales, and the only way to discover these new principles is to pursue higher energies, theoretically and experimentally.

D. P. Roy's article on the current very successful 'Standard Model' describes phenomena at energies less than a hundred times the rest energy of the proton, and correspondingly, length scales about a hundred times smaller than the size of the atomic nucleus. The very success of this model, which is by now rather complex with many parameters, raises the question of what lies at higher energies, and this is addressed in the next article by R. K. Kaul. Traditionally, much of this range has been regarded as unexplorable, but some of the daring ideas to reach such high energies are reviewed by A. Sen. R. Ramachandran sums up with the kind of questions one would like to answer, but with the cautionary note that such exercises in the past have missed the new surprises thrown up by the subject. In addition, he outlines a scenario for the development of the subject in our country.

R. Nityananda

A new look at an old concept

The idea of steric inhibition of resonance is well established and forms part of the standard organic chemistry curriculum. The concept is easy to understand. A substituent on a phenyl ring is generally twisted out of conjugation if two bulky groups are present in the ortho positions. Many examples are known which demonstrate this effect as well as its spectral and chemical consequences.

A more subtle effect is seen in anisoles and related molecules with a single ortho substituent. Instead of a partial reduction in conjugation, an enhancement was proposed by V. Baliah and M. Uma. They argued that in order to reduce steric repulsions, the methoxy group would remain in the plane of the phenyl ring, with the methyl group pointing away from the ortho substituent. Importantly, this preference was suggested to be greater than in the derivative without any ortho substituent (some degree of non-planarity is possible in the latter in view of the absence of steric interactions). This effect was called steric enhancement of resonance (SER). It represents one of the original contributions to stereo-electronic theory to be made from India.

The proof for SER was initially based on trends in dipole moments in a number of phenyl derivatives. Many additional spectral and reactivity features were also interpreted in terms of this effect. Since the magnitude of SER is usually small, results had to be interpreted with caution.

An attractive means of establishing and quantifying SER would be to use modern computational methods, for example by calculating structures and rotational barriers in representative systems. In a complimentary manner, S. R. Gadre and coworkers use the methodology they have perfected over the years to study the

problem of SER (page 130). Using *ab initio* MO wave functions on a number of model systems, the authors have examined the topological features of molecular electrostatic potentials. They find characteristic signatures in the MESP minima which reflect the inhibition of resonance in di-ortho substituted derivatives and also enhancement in mono-ortho counterparts. By placing an additional substituent at the para position, they have established consistency in the computed data.

J. Chandrasekhar

Perception of science

Support for the scientific enterprise depends greatly on the public per-

ception of science. This is especially true in the West but is becoming an increasingly important factor in India.

In an article reprinted in this issue (page 148), Martin Rees analyses the conditions under which discovery and invention flourish best. While his preoccupation with science in Britain may appear somewhat misplaced in this journal, readers would do well to ponder on many aspects of his analysis. Parallels can be readily drawn to the Indian situation, where science today does not have unqualified support and where attracting the best to scientific careers has become extremely difficult. The increasing pressure for research to yield visible dividends is transforming attitudes of scientists and those connected with organiza-

tions and funding of science. What are reliable indicators of success? Interestingly, public perceptions are rarely guided by utility. Martin Rees points out that 'irrelevant subjects' fascinate people most, with dinosaurs and cosmology topping the lists in Britain. In India the 'publish or perish' syndrome appears to have given way to the cry of 'patent or perish'. How do we create an intellectual climate for discovery and invention? How do we emphasize considerations that 'transcend the purely economic'. The article by Rees focusses on these and related issues and should provide a stimulus for future discussions.

CORRESPONDENCE

The Crest of the Peacock

I enjoyed reading a review by R. Sridharan of the book *The Crest of the Peacock, Non-European Roots of Mathematics*, written by G. G. Joseph and I felt I should convey a few remarks on the same. Sridharan's review (*Curr. Sci.*, 1996, 70, 753-754) was admirable and balanced with his generous comment on page 754: '... modern mathematics, as it is understood today, does owe a great deal to the renaissance in Europe, which in turn was a miraculous revival of Greek thought.' Even with regard to our own illustrious mathematicians' 'fundamental contributions to the study of quadratic indeterminate equations,...' and, in particular, (Jayadeva's) 'complete solution of quadratic indeterminate equations by the remarkable Chakravala method', the tendency for anyone to 'overstate his case' or soar, at times, to dizzy heights

of euphoria does perhaps require to be tempered in the light of what appears to be a very fair appraisal, in this connection, by André Weil in (page 24 of) Chapter I entitled 'Protohistory' of his well-known book *Number theory, an approach through history - From Hammurapi to Legendre*: '... For the Indians, of course, the effectiveness of cakravāla could be no more than an experimental fact, based on their treatment of a great many specific cases, some of them of considerable complexity and involving (to their delight, no doubt) quite large numbers. As we shall see, Fermat was the first to perceive the need for a general proof, and Lagrange, the first to publish one. Nevertheless, to have developed the cakravāla and to have applied it successfully to ... difficult numerical cases ... had been no mean achieve-

ment.' Sections IV, VI, VIII and IX of Chapter I of the above-mentioned book contain a detailed authoritative and objective analysis of the 'brilliant discoveries' from India - the kuttaka (=pulveriser) method "recalling to our mind Fermat's 'infinite descent'" the bhāvanā rules ('composition formulae' for special binary quadratic forms) and the 'cakravāla' (= 'the cyclic process') whose 'true originator remains unknown'.

Nobel prizes in X-rays or NMR

In the article '100 years of X-rays and 50 years of NMR' by R. Chidambaram *et al.* (*Curr. Sci.*, 1996, 70, 878-888), the authors have given a list of Nobel prizes won in the disciplines of X-rays or NMR. I feel that the following names should have been included in the table.

1. 1917: C. G. Barkla (Physics): Discovery of characteristic X-rays of elements.
2. 1936: P. Debye (Chemistry): Diffraction of X-rays and electrons in gases
3. 1946: H. J. Muller (Medicine): Pro-

duction of mutations by X-ray irradiation.

Anti-hydrogen

1996 seems to be the year in which many experiments for which ultimate skills were required of physicists have fructified. Nellis and his group at Lawrence Livermore have metallized hydrogen (*Curr. Sci.*, 1996, **70**, 876-877); J. E. Baldwin and his group at Cambridge (*Astron. Astrophys.*, 1996, **306**, L13-L16) have made an important advance in optical astronomy. The resolving power for optical imaging of stars has improved from 1 arcsec to a few milliarcsec, by the technique of aperture synthesis; this may now make it possible to observe spots and other features on stars which could only be seen on the sun so far. Now comes the news on internet from CERN that antimatter has been created; specifically that nine atoms of anti-hydrogen have been 'observed'.

In 1898, Arthur Schuster the British physicist surmised the existence of

antimatter. With Dirac predicting the positron in 1929, Carl Anderson discovering it in 1932, Owen Chamberlin, Emilio Segre and others discovering the antiproton in 1955, it seemed just a matter of time before antihydrogen would be synthesized. Yet one had to wait more than 40 years for this to happen. Big machines like the low energy antiproton ring (LEAR) had to be built in which beams of positrons and antiprotons could be brought together in a cloud of inert xenon gas. The velocities of the antiprotons and the positrons slowed down to be almost the same so that one could capture the other and form a neutral atom.

The temperature too has to be kept below 14 eV (140000 degrees) so that the two component particles do not dissociate. When the antihydrogen atom is formed, being uncharged, it is not bent

by the magnetic field of LEAR, and it flies straight to the silicon detector. The experiment has only 'observed' the decay products of the antihydrogen atom, not the atom itself. The ultimate goal of isolating atoms of antimatter for further studies is still to be achieved. When this happens the comparison of the spectroscopy of the anti-protonic atom and the normal hydrogen atom may prove interesting from the point of view of testing weak violations of basic symmetries. The results of another experiment planned by Samuel Ting (of J particle fame) and others of detecting antimatter in space using an anti-matter spectrometer are eagerly awaited by cosmologists.

The 1996 Crafoord Prize

The Royal Swedish Academy of Sciences has awarded the 1996 Crafoord Prize in the biosciences with particular emphasis on ecology to Sir Robert M. May, University of Oxford, UK, for his pioneering ecological research concerning theoretical analysis of the dynamics of populations, communities and ecosystems. The value of the 1996 Crafoord Prize is US\$ 500,000.

Robert M. May, born in 1936 in Sydney, Australia, began his career as a theoretical physicist but has become, over the last twenty-five years, the person who has exerted the greatest influence on theoretical and empirical ecological research. Through his pioneering achievements, scientists now have a better understanding of the ecological dynamics of individual populations, the interplay between different species and whole ecosystems. Further-

more, his theoretical research has been of great significance for a number of important practical problems.

May's first great contribution concerned the hotly-debated question of whether stability is the cause of the diversity of ecosystems, or whether it is the other way round. May clarified that biological diversity does not automatically generate stability and that a number of different factors in combination lead to the stability of the ecosystem through various disruptions. May's book *Stability and Complexity in Model Ecosystems* (1974) brought about a drastic change of direction in the way of viewing the interaction between different species and the reaction patterns of the ecosystem. The book stimulated innovative research contributions in a number of different fields.

In the young science of nature conservancy biology, May's population dynamics models and theoretical analyses have come to play a fundamental role. This concerns, above all, mapping out what factors are most important for the survival possibilities of small and fragmented plant or animal populations in an environment that is exploited to an ever-increasing degree by man. Crucially, May's theoretical work has pointed at the significance of random events within the diminishing populations, with regard to their prospects of survival for longer periods.

Robert M. May is a professor at the Department of Zoology at the University of Oxford, England. He is also Chairman of the British government's Advisory Council for Science and Technology.

The 1996 Blue Planet Prize

The Asahi Glass Foundation has chosen the recipients of the Fifth Blue Planet Prize, an international award first given in 1992 at the United Nations Conference on Environment and Development in Rio de Janeiro. Presented annually to two recipients, the prize commends individuals, groups, and organizations whose achievements have contributed to the resolution of global environmental problems. The 1996 recipients are: Wallace S. Broecker of the United States, Newberry Professor of Geology at Columbia University, who has made major contributions to our understanding of climate change and global warming through his research into global ocean currents and ocean chemical cycles, particularly the carbon cycle; and the M. S. Swaminathan Research Foundation of India which is a nonprofit organization that supports the promotion of sustainable agriculture and rural development with methods that include the preservation and sustainable utilization of biodiversity, the improvement of soil and plant health using environment-friendly methods, and the creation of ecojobs for rural families. The research foundation, chaired by M. S. Swaminathan, is the first Blue Planet Prize winner from Asia. Each Blue Planet Prize winner will receive ¥50 million.

The M. S. Swaminathan Research Foundation (Madras, India) was founded in 1988 with the goal of promoting research and activism to further rural and agricultural development by environmentally sustainable and socially equitable means. The founder and chairman of this organization is M. S. Swaminathan, the recipient of the first World Food Prize, in 1987, and of the 1986 Albert Einstein World Science Award.

One of the research foundation's major achievements has been the study and conservation of coastal ecosystems, particularly mangrove wetlands. Based on its research into vegetation, soil salinity, and other aspects of mangrove habitats, the research foundation has taken steps to restore degraded wetlands. By promoting sustainable agroforestry and aquaculture, together with the use of organic fertilizers, the M. S. Swaminathan Research Foundation

helps establish integrated coastal management systems that can provide an ecologically sustainable livelihood for coastal families.

The research foundation also conducts a community biodiversity program to rescue endangered plant species from extinction, identifies microorganisms to serve as bioindicators of ecosystem health, and conserves genetic diversity of plant species used as food or in medicinal and other applications. This program includes the creation of a community gene bank to store collected seeds as well as the establishment of guidelines for conducting ecological observations. These are only a few examples of the many activities undertaken by the research foundation to help restore and maintain natural habitats and biological diversity through the application of technology.

In addition, the research foundation promotes the biovillage model of sustainable rural development in India, the People's Republic of China, and Southeast Asia. Further positive results from these efforts are expected in the future. By helping to conserve the natural environment of developing countries while supporting the economic viability of rural communities, the M. S. Swaminathan Research Foundation is playing an important role in the search for solutions to global environmental problems.

In 1990, the research foundation established as its core organization the Centre for Research on Sustainable Agricultural and Rural Development. MSSRF has also set up the Technical Resource Centre for the Implementation of the Equity Provisions of the Convention on Biological Diversity to gather information that will help rural families obtain the recognition and reward due to them for their past and present contributions to genetic conservation and enhancement. The programs of the research foundation are organized under the following five areas.

The first area consists of aligning environmental protection and agricultural productivity in coastal wetlands. In particular, the foundation conducts research into how to tie the ecological security of mangrove forests to the livelihood of coastal communities. With the

support of the International Tropical Timber Foundation, MSSRF conducted a survey of mangrove genetic resources throughout Asia and West Africa. The research foundation then developed a multimedia database and an international information service on mangrove ecosystems.

The second area involves research on the conservation of biodiversity, a fundamental requirement for sustainable agriculture. Specific activities include saving endangered plant species and habitats, promoting the revitalization of genetic conservation traditions of local peoples, and maintaining soil fertility by monitoring microorganisms in soil. The research foundation has also created a gene bank to provide modern techniques for the preservation and use of plant genetic material. Based on its research efforts, MSSRF helps set up sustainable agricultural systems.

The third area consists of the application of ecotechnology to sustainable agriculture. Ecotechnology is a term used to describe the blending of vanguard technologies, including biotechnology, with the ecological wisdom and practices of local communities so as to integrate the ecological and economic strengths of both approaches. Ecotechnology is put into action by the voluntary participation of whole communities, known as biovillages. Similarly, programs have been instituted to create ecojobs, which generate additional food and income from available natural resources in a sustainable manner. The United Nations Educational, Scientific and Cultural Organization (UNESCO) has designated MSSRF as the coordinator for the Asian Ecotechnology Network.

The fourth area is a program entitled Reaching the Unreached, which aims to bring the benefits of new technologies to the economically and socially disadvantaged, especially women and children, and promote gender equity in development.

The fifth area involves training programs and communications tools, including publications. Among its many other activities, the research foundation maintains databases, conducts educational programs, and holds workshops for policy makers and farming families.

Comments on the 'Principle of maximum physical hardness'

In a recent paper, Pearson¹ analyses the proof of Parr and Chattaraj² (PC) for the principle of maximum chemical hardness. He argues that the proof is very general and can also be applied to many observables, other than softness. In particular, using the equation (11) of PC (equation (1) below), he claims to prove the principle of maximum physical hardness. Thus two principles are claimed to be true—one of maximum physical hardness, and the other of maximum chemical hardness.

It is the aim of this letter to show that the arguments of Pearson¹ and those of PC² are in error. We have already commented³ on the paper of PC² and have given a numerical counterexample, which shows that their proof of the principle of maximum chemical hardness is in error. See also the recent paper of Chattaraj, Liu and Parr⁴ which says, 'Recently it has been correctly pointed out³ that the proof by two of us² of the maximum hardness principle is not true in general'. Here we point out why the method adopted by Pearson is incorrect.

As the derivation given by Pearson¹ is based upon that of PC, we consider the arguments given by them. They consider a non-equilibrium ensemble with the distribution $F(\mathbf{r}^N, \mathbf{p}^N)$ and denote the time-dependent expectation value of any observable A by $\bar{A}(t)$. That is,

$\bar{A}(t) = \int d\mathbf{r}^N \int d\mathbf{p}^N A(t) F(\mathbf{r}^N, \mathbf{p}^N)$. They claim that for a class of $F(\mathbf{r}^N, \mathbf{p}^N)$,

$$\bar{A}(0) = \langle A \rangle + \langle A \rangle^{-1} \langle (A - \langle A \rangle)^2 \rangle. \quad (1)$$

Equation (1) is just the equation (5) of Pearson² (equation (11) of PC), rewritten in a slightly different manner. A simple argument is enough to convince the reader that this equation cannot be correct. The left hand side of the equation depends on the non-equilibrium ensemble that one chooses while the right hand side has only equilibrium expectation values in it! In fact, the result of PC is valid specifically for the ensemble, $F(\mathbf{r}^N, \mathbf{p}^N) = \langle A \rangle^{-1} A f(\mathbf{r}^N, \mathbf{p}^N)$, where $f(\mathbf{r}^N, \mathbf{p}^N)$ is the distribution function for the equilibrium ensemble, as may be seen from the equation (8) of PC. Calculating $\bar{A}(0)$ with this gives $\bar{A}(0) = \langle A^2 \rangle / \langle A \rangle$, which is equal to the right hand side of the equation (1), thus verifying the equation (1) for just this particular ensemble. But that does not make the result valid for an arbitrary non-equilibrium ensemble. If in the true spirit of linear response theory, one follows the section 8.5 of the book by Chandler⁵ and takes the non-equilibrium ensemble to be proportional to $e^{-\beta(H + \Delta H)}$, with H being the Hamiltonian, and $\Delta H = -fA$, where f is an applied field that couples to A , then one obtains

$$\bar{A}(0) = \langle A \rangle + \beta f \langle (A - \langle A \rangle)^2 \rangle. \quad (11)$$

As one can choose the coupling field f arbitrarily, it is clear that one does not have any inequality of form $\bar{A}(0) \geq \langle A \rangle$, as claimed by Pearson². As the inequality is not valid, one must clearly view the results obtained by Pearson with caution.

I thank the Alexander von Humboldt Foundation, Germany for supporting this work, by the gift of a computer system.

Biobatteries to utilize bioenergy from fruit and vegetable wastes

Biomass and biowastes represent a large potential energy resource that is renewable on a sustained basis¹. Production of energy from biomass and biowaste resources became globally popular because of decreasing fossil energy supplies and increasing cost and demand for energy, a growing awareness of environmental impact associated with fossil fuel usage as well as surplus global biomass production and potential resource of biowaste produce². Several research studies^{3–7} have highlighted

production of solid, liquid and gaseous fuels from biomass and agricultural waste produce. In the recent past, generation of electricity from biowaste materials and/or municipal garbage was also made possible by converting the waste materials into biogas which in turn was used for the production of electricity based on the most advanced turbine technology².

Although Hwang *et al.*⁸ developed the concept of biocells, later led to their preparation using bacterial membranes

and platinum–silver electrodes to generate voltage in light⁹, attempts to produce electric power directly by electrochemical method from biowaste resources have been limited. Low power dry cells, which are widely used for calculators, wall clocks, video game toys, etc. are now becoming expensive and often non-available in time at village level. Therefore, we have attempted to prepare biobatteries utilizing commonly-available domestic biowaste materials and to use them in low voltage

appliances as alternatives to the conventional low power dry cells (batteries).

Ripe banana and orange peels or vegetable scrap, which are thrown as domestic waste (garbage) were collected and macerated into a fine paste without adding water. Pieces of copper and zinc sheets (0.5 mm thickness) were collected from metal scrap merchants. Copper and zinc plates measuring 10 cm² (4 cm × 2.5 cm) area were cut and selected as electrodes. Each electrode was connected with a short piece of insulated wire through a small hole made at one end of each electrodes. Electrodes were inserted into about 20 g of paste of fruit or vegetable waste taken in (30 ml) plastic vials. Similarly electrodes were inserted directly into

Table 1. Output of power generated in biobatteries prepared from different plant materials (fruits and vegetables). Measurements of power generated in each type of biobattery were repeated on batteries which were constructed using fresh samples of the same material and with the same set of electrodes. Data represent the mean \pm SD of at least five measurements made on different batteries

Material used	Power output of biobattery	
	Volts	mA
Brinjal	0.60 \pm 0.08	0.52 \pm 0.08

*Weeks after preparation of biobatteries.

fresh and intact vegetables/fruits used in this study (Table 1) to make biobatteries. Electric potential generated in each battery was measured by multimeter on DC mode. Each biobattery was found to produce a low voltage power measuring 0.5–0.8 V and 0.2–1.4 mA (Table 1). Therefore a number of biobatteries were connected in series to increase the voltage output. Cumulative output of power generated in 2–4 biobatteries prepared with paste of ripened banana fruit peels was applied to wall clocks or calculators or video game toys through suitable connections using insulated electric wire and was found to make them function without using conventional low power dry cells. Life/durability of newly-constructed biobatteries was assessed by measuring output of power generated in biobatteries at regular time intervals over a period of four weeks and/or using them continuously for wall clocks or calculators. It was found that these batteries exhibited potential and were found functional over a substantial period of time (more than four weeks) without changing electrodes or electrolytic medium (Table 2). Further, it was found that performance of biobatteries could be improved by frequent cleaning of electrodes with water and without disturbing electrolytic medium. The

results showed that among the electrolytic media tested, the paste of ripened banana fruit peels with copper–zinc electrode combination was found effective for the performance of biobatteries. Studies on the evaluation of factors influencing the performance of biobatteries show that the size and quality of both electrodes and medium of electrolyte are important. Further, studies on chemical analysis of electrolyte viz. the paste of fruit and/or vegetable wastes used in biobatteries would be useful to understand the electrochemical mechanism(s) underlying the production of low voltage power in these biobatteries. However, further work on design and construction of biobatteries with different electrode combinations is needed to make them handy, durable and popular.

REMI: A novel method for tagging genes

A. Prakash

Mutagenesis and gene cloning have traditionally been two separate tasks for the geneticist. But the realization that a transposon can be used both as a mutagen and also as a 'gene tag' now enables one to identify and isolate genes at one shot, particularly in systems such as bacteria, yeast, *Drosophila*, *Caenorhabditis* and maize.

But moving transposons around has not been possible in some systems like cellular slime moulds and filamentous fungi. The cloning of genes associated with aberrant phenotypes still remains an arduous task. However the work of Schiestl and Petes¹ has kindled a ray of hope in this direction. Much to their surprise, they found that the transformation frequencies increased considerably when the yeast *Saccharomyces cerevisiae* was transformed with a linearized plasmid together with the restriction enzyme used for linearization. In other words, the restriction enzyme stimulated the integration of the plasmid into cognate restriction sites in the genome.

The evidence suggested a 'simple' mechanism. The restriction enzyme enters the cell along with the linearized vector and cuts at the restriction sites in the genome. The host repair system does its job but at a low frequency, the sticky ends of the vector pair up with the compatible ends generated in the genome by the restriction enzyme. DNA ligase ties the loose ends up.

Encouraged by this finding, Kuspa and Loomis explored the possibility of restriction enzyme mediated integration (REMI) in the obstinate cellular slime mold, *Dictyostelium discoideum*. Much to their delight, they found that the efficiency of transformation increased more than 20-fold and the plasmid integrated more than 70% of the time at the appropriate restriction site².

This raised the prospect of using REMI as a mutagenesis-cum-gene tagging tool in *Dictyostelium discoideum*. The plan of action was simple. Transform the cells with a piece of sticky

DNA carrying a selectable marker in the presence of the appropriate restriction enzyme and select for the transformants. Among the set of transformants generated, hunt for the one with the desirable mutant phenotype. If one is lucky to get a mutant, then isolating the gene into which the vector has inserted is not difficult. Cut the genomic DNA with a rare restriction enzyme. The fragment from the digest carrying the inserted vector can be rescued in *E. coli* and reintroduced into the wild type strain to disrupt the cloned gene by homologous recombination. The high frequency of mutants among the transformants would confirm that the phenotype was indeed because of a mutation in the cloned gene.

Kuspa *et al.* and Adachi *et al.* have executed the plan successfully by cloning the genes involved in cell-cell interaction and cytokinesis in *Dictyostelium discoideum* respectively^{3,4}. REMI has been attempted in other systems, as well. Shi *et al.* have reported REMI enhanced transformation in the rice blast fungus *Magnaportha grisea*⁵. Success has also been reported in the maize pathogenic fungus *Cochleobolus heterostrophus*⁶. However, the presence of restriction enzyme seemed to have had no effect on transformation efficiency in *Neurospora crassa*⁷. There are no explanations as of now, why REMI works in some systems and not in others.

A new technique for physical mapping has been possible by using REMI in league with RFLP mapping. Kuspa and Loomis did REMI with a vector carrying a rare site Apa I within to generate a set of 147 transformants in *Dictyostelium discoideum*. An Apa I digest of the genomic DNA of the transformants yielded 2 fragments carrying the regions of the vector flanking the internal Apa I site. The probing of these 2 fragments with probes from the cloned genes enabled them to map the genes relative to the Apa I sites. Kuspa and Loomis published the detailed maps of

the six chromosomes of *Dictyostelium discoideum* using this technique, REMI-RFLP mapping^{8,9}. This method obviates the need to go in for other genetic data necessary for RFLP mapping.

REMI as a tool for insertional mutagenesis should enable one to identify genes which are not present in functionally redundant forms and not required for viability. The encouraging sign is that restriction enzymes have had no effect on the viability of the cells presumably because of an efficient host-repair system.

There is a point of doubt whether the integration is random¹ or non-random². Despite the possible non-random nature of insertions, the number of transformants could be increased by using different restriction enzymes. REMI also holds a lot of promise in physical mapping in creating chromosomal aberrations and inducing mitotic recombination.

A new tool for plant gene isolation – Transposon traps

C. Santhosh Kumar and K. K. Narayanan

Transposable elements or transposons are segments of DNA present in many organisms that have a tendency to jump from place to place. They were first discovered in maize through the pioneering work of Barbara McClintock¹ much before the DNA structure was known. Similar genetic elements were subsequently discovered and characterized in bacteria, yeast, animals and other plants. Many such mobile elements have now been cloned and sequenced.

A typical transposable element is capable of autonomous transposition and is characterized by specific terminal sequences and an internal sequence which codes for a transposase. The transposase is essential for transposition. In plants, these transposable elements are organized into families. Each transposable element family, typically, consists of an autonomous member and several related non-autonomous or dependent members. All the members of a family have the same termini and create the same length of host sequence duplication at the site of insertion. The transposition event is regulated by the 'autonomous' family member which encodes the full length transposase protein that brings about transposition of all members of that family. Both insertion and excision of the dependent elements are contingent on the presence of a transcriptionally active autonomous element.

Transposons have long been used as a mutagen. Transposon tagging has now become a widely used tool for isolation of genes, both in pro- and eukaryotes. However, this approach, like the conventional mutagenesis approach, suffers from a major limitation. The target loci should have an obvious phenotype, if it has to lend itself to isolation by these approaches.

It is now well known that many genes in any organism, particularly eukaryotes, have no phenotype upon disruption. For example, in the yeast, *Saccharomyces cereviceae*, it is estimated that 60–70% of the genes have no obvious mutant phenotype^{2,3}. Further, genes which are spatially and/or temporally regulated, pose problems in mutagenesis screens. The recently developed approach of using transposon traps, a modification of the transposon tagging technique permits the easy identification and isolation of such genes.

The use of the modified transposon tagging or mutagenesis approach to enable the 'trapping' of genes or their regulatory sequences (enhancers) was pioneered in *Drosophila*⁴. The major modification in this new approach was the use of a synthetic transposon carrying a reporter gene that could confer expression patterns corresponding to the normal expression of the disrupted region. In plants, the potential of this technique was recently demonstrated in

Arabidopsis using the heterologous maize transposable system⁵.

The presence of autonomous and dependent transposable elements in plants offers an unique advantage. Stable transgenic lines, one carrying an immobile transposase source and the other, the dependent element can be produced and maintained. Transposition can be initiated by crossing the two. Further, stable transposants, or the line in which the transposon has moved, can be fixed in the segregating generations. The transposon trap constructs used in this technique, thus have two components. One, the terminal *cis*-acting sequences flanking a reporter gene or the mobile dependent element (Figure 1a and b) and two, the immobilized transposase source (Figure 1c). When separated, each component is stable. When brought together in a single line by crossing, the dependent element transposes to new sites with the help of the constitutively expressed, immobilized autonomous element. The expression of the reporter gene helps to monitor such movements. The genetic region of interest now flanks the dependent element and can be amplified by Inverse Polymerase Chain Reaction (IPCR).

The transposon trap elements can be designed to isolate either the gene itself (gene trap, Figure 1a) or its control element(s) (enhancer trap, Figure 1b). The gene traps are based on the proper integration of a mobile element carrying a reporter gene which lacks its own promoter sequences, into an actively expressed genetic locus. When the trap element integrates into an exon, in the proper reading frame and orientation the reporter gene is expressed. To ensure that the trap works if it gets inserted into an intron, appropriate splicing signals are provided immediately upstream of the reporter gene sequence. The enhancer trap construct carries a minimal (weak) promoter, upstream of the reporter gene. When this element gets inserted into the vicinity of an actively transcribed region, the reporter gene is activated by the neighbouring regula-

Figure 1. Transposable element constructs for trapping genetic regions. The solid arrows represent the conserved terminal sequences required for transposition and SM is the selectable marker. **a**, gene trap construct; S, conserved splicing signal; A, splice acceptor. **b**, enhancer trap construct; TATA, minimal promoter. **c**, immobilized transposase construct; P, strong promoter.

RESEARCH NEWS

tory sequences. The technique of enhancer trapping allows the expression pattern of a large number of genes to be visualized and screened rapidly.

The use of gene and enhancer trap elements can be an attractive alternative to other gene isolation techniques in plants. The generation of large number of transposon insertions by simply crossing a small number of transgenic parental lines and visual selection based on reporter gene expression make this method very efficient. It has now been established that the maize transposable

elements work in several heterologous hosts and this extends the application of this technique to species in which transposons are yet to be identified.

COUNCIL OF SCIENTIFIC AND INDUSTRIAL RESEARCH (CSIR), NEW DELHI, INDIA

ADVERTISEMENT NO. 8/96

POSITION: DIRECTOR, CENTRE FOR BIOTECHNOLOGY (CBT), DELHI.

CSIR, the premier agency established by the Government of India to undertake scientific and industrial research in the country, is looking for a suitable scientist/technologist for the post of Director for its Centre for Biotechnology (CBT), Delhi. CBT is devoted to producing and supplying important biochemicals needed in biological research, to upgrade the existing technologies by exploiting new developments in the field of biotechnology, to conduct research on indigenously available natural products (venoms, gums, etc.) with a view to isolating chemicals needed for research and to exploit their commercial potential; and to help in the off-the-shelf supply of research chemicals and biochemicals required for advanced biological research. The major R&D programmes of the Centre relate to allergy and immunology, diagnostics, genetic engineering, bio-organics and high-tech reagents. The Centre has national facilities for the synthesis of oligonucleotides and for import and distribution of enzymes and fine chemicals.

Fishery genetics: An emerging discipline

B. K. Padhi and R. K. Mandal

Fishery genetics has grown rapidly in the last one and a half decades accumulating so much of knowledge and information of applied interest that it can be assigned the status of a discipline.

GENETICS has now acquired an important status in fishery science. There is growing interest on the subject as revealed by multifold increase in the number of research papers on cytogenetics, molecular, quantitative and biochemical genetics¹, suggesting the utility of applications of genetic principles and methods for improving the fish breeding programme, for documenting genetic diversity in natural populations² and developing proper management programmes to conserve genetic diversity³. In the present article the developments, scope and importance of the subject are discussed.

Fishery genetics – a definition

It is tempting to provide a comprehensive definition to this growing discipline. Since the subject concerns the applied aspects of fish culture and natural fishery, it appears more appropriate calling the subject 'fishery genetics' rather than 'fish genetics'.

Fishery genetics may be defined as the application of genetic principles and methods for increasing aquaculture productivity by genetically modifying fish stocks and for the management of fish populations to obtain maximum sustainable yield without affecting the genetic diversity.

Factors leading to the growth of the subject

The interest in fishery genetics grew primarily for two reasons. It was gradually realized that the anthropogenic factors such as over-exploitation of natural fishery from open waters, modification of aquatic environment by pollution load, development programmes like damming of rivers, etc. have led to a decline of wild populations and these have genetic and evolutionary consequences⁴. Also, the necessity was felt for improving aquaculture productivity by genetic improvement of fish stocks primarily to meet the increasing demand on fish proteins. The implications of each of these factors are discussed below briefly.

Over-exploitation and habitat modification

Effect on production trait

Evidence shows that traits such as growth rate and age of maturity of brood fish and feed conversion efficiency

are heritable and cultured populations of fish respond to selection for these characters⁵. It is now recognized that harvesting can exert an evolutionary selection pressure that may bring about genetical changes⁶. For example, most fishing gear selects a certain size of fish. Big hooks cannot catch small fish and wide meshes allow small individuals to wriggle through. There is a considerable variation in growth rates in fish of the same age group. Thus, it is expected that the fishing gear selects out fast growers in an age class. If growth rate is partly determined by the genetic factors, it is likely that prolonged inadvertent selection against fast growth will lead to selection of slow growers. Experiments with tilapia (*Oreochromis mossambica*) showed that harvesting has a negative selection pressure⁷. The other traits which harvesting can affect are the ability to escape net, body proportions, number of eggs per unit weight, etc.

Effective population size

Excessive mortality due to over-harvest or habitat modification and impairment of reproductive ability because of pollution load⁸ reduces the effective population size. Effective population size means the number of reproductively active individuals in a population. If the population size gets small, it results in inbreeding and genetic drift.

Effects of stock introduction and unwanted hybridization

The term 'introduction', in this context, means transfer of fish by man into waters outside of their native ranges. In other words, any intentional or accidental release of fish by human activity into the natural waters is considered introduction⁹. Introduction has ecological and genetic effects. The ecological effects of introduction include processes or mechanisms such as competition, predation and habitat alteration. The genetic effects of introduction leads to alteration of gene pools of indigenous species. The alteration may be direct as in the case of introgression (gene flow) or indirect such as reduction of effective population size, making natural population vulnerable to the effects of genetic drift. Intra-specific or inter-stock crossing leads to reduction of

B. K. Padhi and R. K. Mandal are in the Department of Biochemistry, Bose Institute, Calcutta 700 054, India.

genetic variability between the populations (a homogenization effect)¹⁰. Therefore, there has been a growing interest in identifying F1 and F2 hybrid in nature and distinguishing them and also to document genetic introgression due to back-crossing of the F1 hybrid with parental species. Therefore, a number of research papers appeared, which dealt with introgressive hybridization primarily using isozymes as the tool¹¹ supplemented by mitochondrial DNA analysis. A few researchers used nuclear DNA RFLP¹².

Aquaculture

Genetic studies in aquaculture have witnessed two different approaches; firstly, to reveal the genetic impacts of using small and closed populations in commercial hatchery; secondly, to improve the genetic potential of fish stock by selective breeding, chromosomal engineering, gene manipulation, sex and fertility control. The first aspect primarily aims at reducing/avoiding the improper breeding practices, while the second aspect is to develop superior strains of fish.

In the early eighties, many research papers appeared which recorded low quality of fish seed produced due to improper breeding practices¹³. Around the same time the feasibility of quick methods, such as chromosome¹⁴ and gene¹⁵ manipulation to improve the genetic performance of fish came to limelight. Chromosome manipulation (by thermal, pressure and chemical shock) in fish was an interesting development. Because, unlike other vertebrates, fishes can tolerate change in ploidy level, and thus bypass long-term selective breeding programme, while trying to obtain superior variety.

Scope of applied genetic research in fishery science

At present there lies ample scope for applied genetic research in fishery science. Major areas needing proper research input for the conservation and productivity improvement of this renewable resource are as follows:

Stock identification

Identification and documentation of intra-specific genetic polymorphism occurring in different populations occupying different ecological zones within a species is of enormous practical significance. A number of research papers on this aspect are already available primarily from USA and other developed countries. However, this is a very virgin field in India and many other developing nations, where most of the fish biodiversity exist. This study is useful in selective breeding programme in hatchery, devising policy on the rehabili-

tation and conservation of a declining stock, biodiversity documentation, study of phylogeography and systematics and proper utilization of cryopreserved gametes¹⁶.

Stock/species introduction

Introduction is an useful approach to augment fish production by supplementing natural recruitment. However, introduction of exotic species/non-native stock for this purpose has been a matter of genetic concern. Many papers published recently pointed out that inter-stock crossing could lead to stock admixture and reduction of genetic biodiversity^{17,18}, which in turn would affect the future breeding programme.

Dowling *et al.*¹⁹ pointed out that introgressive hybridization was an evolutionary factor which could bring about genetic variability. On the contrary, many researchers viewed that introgression would cause genetic contamination² and decline of populations by bringing about the rearrangement in co-adapted gene complexes²⁰.

However, many relevant questions still remain; i) How much gene flow between or within the species is permissible? ii) Is the reduced population size after genetic interaction of inter-specific hybrid due to rearrangement of co-adapted genes or due to reduced fecundity (that is partial sterility) of the later generation hybrids? iii) How much threat does 'introduction' – as a factor, pose to the intra- and inter-specific genetic diversity? Further studies on measuring of gene flow among the populations and between the species would be of great importance.

Stock improvement

The remarkable developments in aquaculture are primarily due to availability of fish seed by artificial breeding and improved management practices such as supplementary feeding, use of clean water, eradication of pests and weeds, etc. Now that the technology of production and rearing has largely been mastered for many species of culturable fishes, it is reasonable to look for genetic techniques to increase aquaculture productivity. Genetic modification of the organism to increase the growth rate has been the primary goal of stock improvement programme to improve the aquaculture productivity. Enormous research efforts have already been put into this. The technical approaches have been selective breeding and hybridization, chromosome and gene manipulation, fertility and sex control. The practical benefit of genetic improvement programmes have already been manifested in Norwegian salmon industry, where accumulated selective breeding for 15 years showed improved productivity. Some scientists have

applied integrated approach (use of more than one technique) to develop better strains. For example, joint application of endocrine and cytogenetic approach to obtain monosex fish²¹ and production of tetraploid fish by chromosome manipulation and hybridizing it with the related diploid species to obtain triploid individuals with better characteristics.

In spite of methodological developments and so much of experience that is being recorded in the literature, quite a lot is yet to be done to fulfil the genetic goal set by the aquaculture industry for developing superior strains of fishes.

Monitoring genetic change

Breeding of a small-sized population, in nature or in hatchery, leads to loss of intra-population variability because of selection (intentional or unintentional), genetic drift and inbreeding. Reduction of genetic variability can be monitored in terms of reductions of heterozygosity by analysing the frequency of polymorphic loci or average number of alleles per locus. This would be useful in maintaining effective population size.

Indian scenario in fishery genetics research and education

In India, some research efforts were made on chromosome engineering²², transgenic fish production²³, sex control by endocrine and cytogenetic manipulation^{21,24}, cryopreservation of gametes²⁵, genetic stock identification²⁶ and hybrid identification²⁷. However, a lot more research efforts on fishery genetics are needed to generate knowledge, process and products of applied interest in aquaculture and capture fishery management.

Fishery genetics has not found its proper place in fishery education in the country. Fishery is taught as a special paper in M Sc Zoology courses in several Universities and there are about a dozen fishery colleges affiliated to agricultural/veterinary universities, offering courses on B FSc and M FSc. A preliminary survey revealed that fishery genetics is either not included in the syllabus or if some preliminary topics are included, they are not dealt with seriously. Although Indian Council of Agricultural Research has set up the National Bureau of Fish Genetic Resources in Lucknow more than a decade ago, there is a general apathy towards fishery genetics among the academicians and policy makers associated with fishery education and research.

Concluding remarks

Annual world landings of aquatic resources have increased more than four-fold; from 21.9 million tonnes

per year between 1952 and 99.5 million tonnes in 1989 (ref. 28). The larger share of this production came from the capture fishery sector, which has been over-exploited, leading to decline of fish biodiversity. An analysis revealed that 20% (1800 species) of the world's freshwater species are severely threatened²⁸. On the other hand, aquaculture provides greater scope for increasing fish production and productivity. Thus, fishery genetics as a growing discipline will have an important role to play in future for conservation and management of natural fishery and increasing the aquaculture productivity.

Protein–DNA and protein–protein interactions in λ -repressor/operator system: A review

Siddhartha Roy

Department of Biophysics, Bose Institute, P 1/12 C.I.T. Scheme VII M, Calcutta 700 054, India.

λ -repressor is a two-domain protein. The N-terminal domain interacts with the DNA, while the C-terminal domain is responsible for all protein–protein interactions. Functioning of the repressor in the natural context implied that the two domains should have flexibility. Denaturation and fluorescence anisotropy studies, however, demonstrate that the situation is more complex. It is likely that in the free repressor the two domains interact with each other and are not completely free to rotate. The binding of operator to N-terminal domain, however, causes a conformational change in the C-terminal domain. This conformational change leads to change in protein–protein interaction. One of the major changes that is seen, is that of the role of the C-terminal tail region in protein–protein interaction. It is hypothesized that the role of the conformational change is to couple the specific operator binding information to the protein–protein interaction, which may lead to increased specificity at the required sites.

REGULATION of information flow from DNA to RNA to protein is at the center of all biological phenomena. This regulation, both when following an internal programme and in response to an external stimulus, is primarily at the level of transcription. The regulation of transcription is a very complex process in eukaryotes and is not well understood. Even the basal transcription in yeast may take tens of protein factors¹. Such complex systems are difficult to study from structural points of view with the present level of technology. Prokaryotic and phage regulatory systems are often much simpler and at the same time incorporate many of the regulatory features of the higher eukaryotes^{2,3}. Thus, they are ideally suited for investigations by structural and biophysical techniques.

Many of the prokaryotic regulatory systems have been studied in fair details by genetic and molecular biological techniques. They include *Lac*, *Gal*, *Trp*, *deo* and *Ara* operon of *E. coli*⁷ and lytic-lysogenic regulatory system of bacteriophage λ ^{8–10}. Protein components of these and several other prokaryotic regulatory systems are well characterized and nature of the regulatory events have been described. Crystal and NMR structures of some of these proteins and some fragments have also been eluci-

dated^{11–14}. Thus, several of these systems are poised for further investigations of the regulatory events in quantitative terms and at atomic levels.

My laboratory has focused attention on the lytic-lysogenic switching system of bacteriophage λ . Extensive genetic and biochemical work from the early '70s by Mark Ptashne and coworkers has established the components and the basic nature of the system. The switching system consists of three contiguous 17 base pair sequences known as the right operator sites, O_{R1} , O_{R2} and O_{R3} , and two proteins, λ -repressor and *cro*. This collection of operator sites, known as the right operator or O_R , also contains two promoters, P_{RM} and P_R (Figure 1). The structural gene of the λ -repressor is under the control of the promoter P_{RM} and the structural gene of the *cro* is under the control of the promoter P_R .

The *cro* protein is a homodimer of a polypeptide chain of 66 amino acids and binds to the three operator sites, in the order of decreasing affinity, $O_{R3} > O_{R2} > O_{R1}$ (ref. 15). The *cro* protein functions as a down regulator of transcription¹⁶. In contrast, the λ -repressor is a multifunctional protein that acts as both *up* and *down* regulator depending on the context^{17,18}. In addition, λ -repressor binds to the three operator sites, co-operatively, in the order of decreasing affinity $O_{R1} > O_{R2} > O_{R3}$ (ref. 19). This co-operative binding is vital for the functioning of the genetic switch, since, otherwise normal non-cooperative mutants lose their ability to lysogenize completely. In the lysogenic state, two repressor molecules occupy O_{R1} and O_{R2} , and activate the promoter P_{RM} and repressing the promoter P_R , thus shutting off *cro* synthesis and continuing λ -repressor synthesis. The continuing repressor synthesis is required to replenish the dilution losses due to cell division and growth. No other gene is transcribed in this state and the steady-state is maintained. Following DNA damage, the *recA* protein cleaves the repressor, destroying the co-operative binding and weakening the affinity for the operator sites. This throws the switch, shutting off the repressor synthesis and initiating *cro* synthesis, resulting in entry into the lytic pathway (Figure 2).

It is clear from the above description of the operation of the switch, that the λ -repressor plays the central role in switching the phage from lysogenic to the lytic mode

Figure 1. DNA sequence of right operator region of bacteriophage λ .

Figure 2. Depiction of $OR1-OR2/\lambda$ -repressor complex in lysogenic state and subsequent induction to lytic pathway. The upper half of the figure represents two repressor molecules bound to the operator sites $OR1-OR2$ and preventing transcription from P_R but activating transcription from P_{RM} . The middle part of the figure depicts the cleavage of the repressor by RecA and the bottom part represents the unbound form of DNA in which transcription from P_R takes place.

of growth. λ -repressor monomer consists of a single polypeptide chain of 236 amino acids. The monomers associate to form dimers, tetramers, octamers and at

very high protein concentrations, higher order structures^{20,21}. The chain folds into two domains, 1–92 and 132–236 with a hinge region in between the two domains²⁰. The N-terminal domain contains the helix–turn–helix motif, commonly found in many prokaryotic DNA-binding proteins, and has been shown to bind operator DNA²². The C-terminal domain is largely responsible for dimer and higher order aggregate formation as well as protein–protein contact needed for co-operative binding to multiple operator sites²³. Very little is known about the structure of the hinge region or its function.

A problem of great magnitude, such as regulation of gene expression and genetic switching, requires study of many systems. Understanding of their diversity and underlying unity is essential to unravel the complexity of the problem. One or a few emerge as the paradigm. *Lac* and λ regulatory systems have perhaps emerged as the best characterized systems in terms of genetics, biochemistry and structure. Thus, the stage was set for quantitative biophysical studies to understand the regulation in quantitative terms. Seminal work by Gary Ackers and co-workers^{24–26} in the eighties has established the basic physicochemical parameters of the system, such as binding affinities, cooperative interaction energies, etc. The task now is to elucidate conformational and dynamical aspects of the system, so that finally it can be understood at the residue or the atomic level.

My laboratory has undertaken a long term programme to investigate the biophysical aspects of functioning of the λ genetic switch, in general and the interactions of λ -repressor, the most important component of the switch, in particular. The interactions of λ -repressor with the operator sites have been studied in detail by Gary Ackers and his co-workers, using quantitative footprinting^{24,25}. They measured the net co-operative interaction energies, which turn out to be small, around 2–3 kcal/mole. This net co-operative interaction energy consists of at least the following elements: (i) The

proximity effect of bringing the two adjacent molecules to one another. This effect, in analogy to the chelate effect, should be entropic in origin. (ii) The protein-protein interaction energy while bound to the two operator sites. (iii) The DNA binding energy. (iv) The protein distortion energy. The last two effects oppose the first two. The decomposition of the net co-operative interaction energy to its constituent parts is essential if one has to understand co-operatively in molecular and atomic terms. Thus, we have focused our attention on these individual effects, concentrating on protein-protein interaction, DNA binding and DNA-induced conformational change.

Domain-domain interaction in λ -repressor

It was generally believed that the two domains of the repressor may be free to rotate, with the hinge acting as a connecting flexible region. This putative flexibility was thought to be important in the functioning of the repressor since, the repressor can co-operatively bind to two operator sites separated by variable number of base pairs. The crystal structure of the isolated N-terminal domain as well as its complex with the O_L1 , is known^{12,22}. Very little information on the C-terminal domain and hinge structure is, however, available. NMR studies of the whole repressor molecules suggested motional freedom of the N-terminal domain due to the observed line narrowing²⁷. The experiments were, however, done at very high protein concentrations (3–5 mM) where λ -repressor is known to oligomerize to higher order structures, which may have properties different from those of the free dimer. Equilibrium denaturation of λ -repressor by urea has been studied using fluorescence and circular dichroism spectroscopy²⁸. λ -repressor contains three tryptophan residues, 129, 142, 230 and three cysteine residues, 180, 215 and 219. The λ -repressor denatures in three distinct phases: in the first phase, which is centered around 2.0 M, there is a significant red shift of tryptophan fluorescence, but little change in far-UV circular dichroism spectrum. The second phase, centered around 3.5 M urea, is characterized by large decrease of the CD spectral intensity, but no change in the tryptophan fluorescence spectrum. The third phase occurs at very high urea concentrations, above 8 M urea. Fluorescence polarization studies indicate that the repressor remains as a dimer and the dissociation into monomers occurs around 7.5 M urea. As mentioned above the λ -repressor contains three cysteine residues, all of which are situated in the C-terminal domain. The attempted reaction of the cysteines with DTNB indicated that the cysteines were unreactive in the native state. Exhaustive protease digestion, however, produced near-full reactivity, suggesting inaccessibility as the cause of inertness. This lack of reactivity is pre-

served even at 6 M urea, suggesting that the first two phases of denaturation do not involve total denaturation of the C-terminal domain. One sulfhydryl group becomes available for reaction at urea concentrations higher than 8 M. The intact repressor can be cleaved by papain into 1–92 and 132–236 fragments, which can be isolated²⁰. Denaturation of the isolated N-terminal domain coincides with the second phase of the denaturation, suggesting that the second phase is the denaturation of the N-terminal domain. This also agrees with the lack of tryptophan residues in this domain (no change in tryptophan fluorescence) and high alpha helical content (large change in CD signal). The nature of the first transition thus could be partial denaturation of the C-terminal domain or the hinge region or both and hence, denaturation of the isolated 132–236 fragment was studied. This fragment still shows the first phase of the denaturation, only the mid-point shifts to around 1.0 M urea concentration. This suggests that the first phase of the denaturation involves denaturation of the part of the C-terminal domain. Under controlled proteolysis condition, the repressor can be cleaved by papain to produce the fragment 93–236 (ref. 20). This fragment has also been purified. The equilibrium denaturation shows that the first denaturation phase is centered around 1.4 M urea. These data suggest that the presence of the hinge region and the N-terminal domain confers additional stability to the part of the C-terminal domain which undergoes denaturation in low urea concentrations. Since the fragment 132–236 preserves the first transition involving tryptophan residues, W142 or W230 must be responsible for the red shift. N-Bromosuccinimide modification studies suggest that W230 is highly red shifted (λ_{\max} around 345 nm). Since the first transition involves red shift of one tryptophan residue having λ_{\max} of less than 340 nm, it suggests that W142 may be the tryptophan involved in the first transition. Thus, it may be concluded that the N-terminal domain, the hinge and the N-terminal part of the C-terminal domain may interact with each other in the native repressor and the two domains may not be completely isolated. The interaction energy, however, may be small (approximately 1 kcal/mole; obtained from the extrapolation to zero urea concentrations), suggesting that the freedom of internal rotation may be gained by sacrifice of only around 1 kcal/mole energy.

The concept of interacting domains enunciated above received strong backing from fluorescence polarization studies. As mentioned above, the repressor lacked reactive cysteine groups to be tagged with appropriate fluorophores. The protein may be labelled with dansyl chloride without the loss of biological activity²⁹. Rotational correlation time, under conditions known to favour the dimer, was measured from Perrin plot. The result obtained was consistent with a globular dimeric protein of molecular weight of 52 kDa. If the domains

were completely free to rotate with respect to each other, then this would have led to smaller values of the rotational correlation time.

Self-assembly of λ -repressor

The preparation of dansyl labelled repressor with full biological activity produced a unique opportunity to study protein association in λ -repressor. λ -repressor is known to be in a monomeric state at concentrations below nanomolar level. It dimerizes with an association constant of about 10^8 M^{-1} and remains predominantly dimeric till micromolar concentrations^{26,30}. Early qualitative work suggested that beyond $1 \mu\text{M}$, λ -repressor formed tetramer, octamer and eventually higher order structure²¹. The self-assembly was not known in quantitative terms. A quantitative measurement of the self-assembly is important to elucidate the nature of biologically important protein-protein interaction.

Using fluorescence anisotropy measurement, the assembly profile of λ -repressor from dimer to tetramer was determined. Under the solution conditions used (i.e. in the absence of divalent cations), the tetramer to octamer transitions was largely decoupled from the dimer to tetramer transition. The temperature dependence of the assembly profile showed the dimer to tetramer assembly to be highly temperature dependent and enthalpy driven with a ΔH of around -34 kcal/mole . The binding of the single operator site fragment O_R1 caused weakening of protein-protein interaction around ambient temperature. At about the same time other laboratories had reported a concerted transition from dimer to octamer approximately the same concentration range, using ultracentrifugation³¹. Their solution conditions, however, included millimolar concentrations of Ca^{++} and Mg^{++} . Controversy about the correct model of self-assembly lingered on for some more years, until recently, when two studies from different laboratories resolved the issue. Gary Ackers and co-workers have shown that the original concerted dimer to octamer model was based on inaccurate analysis of the ultracentrifuge data and the revised data showed much lower degree of coupling between the two transitions under the conditions previously reported to favour concerted dimer to octamer assembly (G. A. Ackers personal communication). Studies in our laboratory suggested that millimolar divalent cation concentrations promote significant coupling of the two transitions and in the absence of divalent cations only a small degree of coupling is seen³². Whether the effects of divalent cations on protein association have corresponding effect on protein-protein interaction responsible for binding co-operativity, is unknown at the present moment.

Operator-induced conformational change

The arguments presented above suggest that the N- and the C-terminal domains in λ -repressor may not be free to rotate. That raises an apparent dilemma. The various operator site pairs are separated by a variable number of base pairs (four through seven) and the repressor binds to these pairs of operator sites with co-operative interaction energies of similar magnitude. When the operator sites were separated by a much longer stretch of DNA on an artificial construct, the repressor still bound to these operator sites co-operatively³³. Such insensitivity to the length of the intervening DNA suggests considerable flexibility in the C-terminal domain, since the N-terminal domain remains anchored to the operator site. It is possible that co-operative contact occurs between two operator sites bound dimers at the cost of N-terminal domain-C-terminal domain interaction. The other possibility is that binding of repressor to the operator site may lead to a global conformational change, leading to facilitated freedom of movement of the C-terminal domain. The possibility that binding of the operator site to the λ -repressor produces a global conformational change was investigated, using intrinsic tryptophan fluorescence and an environment-sensitive fluorescence probe, bis-ANS³⁴. All the tryptophans of λ -repressor are situated away from the N-terminal domain and hence the DNA binding site. The binding of an oligonucleotide containing an isolated operator site, O_R1 , leads to significant quenching of tryptophan fluorescence and a modest shift of emission maximum. Since all the tryptophans are situated away from the DNA binding site, the operator-induced change is likely to be transmitted to the C-terminal domain. Bis-ANS is an environment-sensitive probe with affinity for the apolar sites of proteins. Bis-ANS binds to the C-terminal domain of λ -repressor. Binding of the oligonucleotide containing O_R1 operator site causes fluorescence enhancement of the bound bis-ANS, indicating a global conformational change occurring upon binding of the oligonucleotide containing the operator site. Whether such a global conformational change leads to increased freedom of movement of the C-terminal domain, remains to be seen.

Role of C-terminal tail in protein association

During studies of protein association, it was observed that a shift of emission maximum of tryptophan fluorescence takes place during protein association at the concentration range that is known to promote dimer to tetramer association under the conditions used. This suggested that one of the three tryptophans may be at or near the protein-protein contact site and its identification may lead to localization of part of the dimer-dimer

contact site. Acrylamide quenching experiments showed that accessibility of at least one tryptophan is significantly different in the dimeric and tetrameric state³⁵. This tryptophan also shifts its emission maximum from very red, 345 nm in the dimer to very blue 334 nm in the tetramer. N-Bromosuccinimide oxidation leaves one of the tryptophans unmodified in the tetrameric state, but not in the dimeric state. Peptide mapping, amino acid analysis and sequencing suggest that this tryptophan is W230. Based on this information we created a site-directed mutant F235C for attachment of fluorescence probe to the tail region of the protein. This sulfhydryl residue can be selectively labelled with an environment-sensitive probe, acrylodan. Acrylodan 235C-labelled protein showed significant shift of emission maximum and fluorescence enhancement upon association from dimer to tetramer. Thus, we conclude that the whole C-terminal tail region of the protein may be involved in the dimer-dimer association.

Interestingly, many non-cooperative mutants have been isolated by several groups and some of them are mapped in the C-terminal tail region of the protein^{23,36}. But most of the mutants are mapped in the other parts of the C-terminal domain. Several of the mutant proteins have been studied in respect to their association properties and DNA-binding abilities. The only well-characterized tail mutation is S228N. Although this was originally characterized as a non-cooperative mutant¹⁰, recent studies have shown that it is defective in monomer-dimer association and not co-operativity defective as was originally suggested^{37,38}. Sedimentation velocity ultracentrifugation studies have shown that S228N does not associate beyond the dimer stage, i.e. aggregation defective. This study pointed towards the fact that the role of the tail in co-operative contact and free protein association may be different. Since there are two excellent markers, W230 and C235, for the tail region, we decided to explore this interesting issue further.

A double operator site, O_{R1}-O_{R2}, containing oligonucleotide was synthesized. Binding of λ -repressor to this oligonucleotide leads to protein-protein contact, while the repressor dimers remain bound to the two adjacent operator sites. This complex was studied using acrylamide quenching as a tool³⁵. The acrylamide quenching pattern of the O_{R1}-O_{R2}/repressor complex is very similar to the dimer, indicating no change of environment of W230. Acrylodan-labelled protein at cysteine 235 also shows different behaviour. The AC235-repressor shows dramatic quenching of AC fluorescence upon single operator titration and similar effect is seen with double operator titration. This is in contrast to the fluorescence enhancement seen in the free repressor undergoing tetramer association. The thermodynamics of the protein association is also dramatically different in free protein tetramer formation and co-operative contact. Whereas the former is strongly enthalpy driven, the

latter is iso-enthalpic and entropy driven. The difference in thermodynamics and the role of the C-terminal tail may be due to spatial constraint imposed upon the protein-protein association by the proximity of the two adjacent operator sites and rigidity of the DNA, or it may be due to a change in nature of the protein-protein interface, induced by operator binding. The protein-protein association in single operator site bound dimer is, like the co-operative interaction energy, iso-enthalpic and entropy driven. The behaviour of W230 is also unlike the free tetramer association in the operator bound dimer association. We may conclude from these studies that free dimer association is significantly different from co-operative dimer-dimer contacts and this difference is a result of the global conformational change induced by the binding of the operator.

Binding of λ -repressor also induces a conformational change in the double operator fragment O_{R1}-O_{R2} as seen by difference circular dichroism spectra. This distortion is not seen in a control oligonucleotide of the same composition where the two operators have been placed on different sides of the DNA by insertion of half turn of the DNA. This suggests that co-operative interaction of the λ -repressor is responsible for the distortion of the DNA and the distortion probably originates from the intervening stretch between O_{R1} and O_{R2}. This result is consistent with DNase I hypersensitive band seen in intervening sequence by quantitative footprint experiments³⁹.

Significance of the operator-induced conformational change

Based on the fact that the operator binding causes a global conformational change in the repressor, which ultimately leads to change of protein-protein interaction and DNA distortion induced by protein-protein co-operative contact, we propose that the λ -repressor/O_{R1}-O_{R2} complex is a strongly coupled system, in which, operator binding, DNA distortion and protein-protein interaction are strongly coupled. This can be understood in greater detail from the thermodynamic cycle depicted in Figure 3. The sum of intrinsic interaction energies (including entropic gain due to proximity effect) is not fully expressed, and the observed binding energy is less.

$$\Delta G_{ob} = \Delta G_{dis} + \Delta G_{bin} + \Delta G_{int}.$$

ΔG_{ob} is lower than $\Delta G_{int} + \Delta G_{bin}$. The difference is used to pay for the distortion of the DNA and protein. Clearly the central question is, what is the role of DNA and protein distortion in the system?

One possible answer is that the distortions are needed to bring the system in right geometric disposition. We feel that this is a red herring, and the real significance lies elsewhere. It was previously observed that

Figure 3. Decomposition of net co-operative interaction energy into individual interaction energies using binding cycle. The transformation from unbound DNA and unbound protein (lower left corner) to co-operatively bound complex (lower right hand corner) releases ΔG_{oh} . The free repressor C-terminal domain is represented by a square, whereas the operator-bound conformation is represented by an ellipse. The transformation from lower left to upper left, represents distortion of DNA and protein and is represented by ΔG_{dis} . The transformation from upper left to upper right represents binding energy of the distorted states, ΔG_{bin} . The transformation from upper right to lower right represents the protein-protein interaction energy while the repressor molecules are bound to the two adjacent operators, ΔG_{int} .

non-specific DNA sequences do not induce the conformational change induced by specific operator sequence. This suggests that the conformational change may be a mechanism to couple the correct recognition of sequence to appropriate protein-protein interaction and subsequent complex formation. This may prevent formation of a complex at inappropriate sequences.

Is there any other possible role for the conformational change and strong couple? In the classical model of *down regulation*, the repressor down regulates transcription by excluding the polymerase from the promoter. Recent work has suggested that this may not be the case⁴⁰. A number of studies have shown that polymerase and repressor can coexist on the DNA^{40,41}. Adhya and coworkers have hypothesized that like positive regulation, the negative regulation also takes place through repressor-polymerase protein-protein contact². In a collaborative unpublished work⁴² we have shown that under defined *in vitro* conditions, in the *gal* system, induction of transcription occurs at repressor concentrations much above the dissociation constant of the operator-repressor complex. This suggests that obligatory steric occlusion may not be the mechanism of *down regulation* in all cases and the repressor-polymerase contact should be considered as a serious possibility for the mechanism. If such a possibility turns out to be true, I speculate that another role for the operator-induced

conformational change may be to present the correct interface for interaction with RNA polymerase, causing *down regulation*. In any non-specifically bound situation, such interface is not available for interaction with the RNA polymerase, thus decreasing the potential for causing harm elsewhere.

In summary, the regulatory system of bacteriophage λ has been investigated in detail from genetic, biochemical and to a moderate extent from structural points of view. Further structural investigations remain to be done. Quantitative biophysical parameters have been established from Gary Ackers' laboratory. We have shown the importance of conformational change and dynamics in the functioning of such a regulatory system. The challenge is now to understand the control and switching of transcription at the atomic level and in quantitative terms.

REVIEW ARTICLE

Oxidative phenol coupling: A key step for the biomimetic synthesis of many important natural products

Tarasankar Pal and Anjali Pal

Department of Chemistry, Indian Institute of Technology, Kharagpur 721 302, India

We present here the oxidative phenol coupling (OPC) reaction utilizing various reagents and leading to biomimetic synthesis of many natural polyphenolics.

OXIDATIVE phenol coupling (OPC) reaction incarnates a 'C–C' or 'C–O' bond between phenolic moieties through oxidation as delineated in all the schemes described here. OPC thus becomes a fundamental method for the synthesis of hydroxylated biaryls¹. The reaction has previously been of little significance and synthetic value because it could not be controlled to the desired step. Unwanted side products were also formed if the aromatic substrate had several sterically or electronically comparable positions. But, later, it gained tremendous attention with the discovery of a prodigious number of natural products such as lignans,² xanthenes³ and a wide variety of tetrahydroisoquinoline alkaloids⁴, which had been assumed^{5–7} and later confirmed to be biosynthesized involving OPC of appropriate precursors. This reaction thus gained a new dimension by

providing an excellent laboratory method for mimicking certain biosynthetic steps. This has initiated extensive studies on the reaction on a wide variety of phenolic compounds, leading to the successful biomimetic synthesis of many natural products, viz. gossypol analogue,⁸ a well-known male antifertility agent (Scheme 1); euphorbetin and isoeuphorbetin⁹, two coumarin dimers (Scheme 2); several alkaloids¹⁰; dimers

Scheme 1.

Scheme 2.

of hydroxylated phenanthrenes and dihydro phenanthrenes¹¹, constituents of high altitude Himalayan orchids; polyhydroxy flavones¹²; lignans¹³; xanthenes¹⁴ and many more compounds. The importance of the reaction is also clear in the light of different medicinal and biological utility of many coupled products. Among these properties are antitumour-anticancer activity, hormonal characteristics, colouring properties, and drug activity. Often attempts to duplicate a natural product lead to the formation of another isomer¹⁵ not occurring in nature. With time, extensive diversification of the OPC reaction has grown with respect to variations in the phenolic and related substrates as well as through the availability of newer oxidizing agents and optimization of the reaction conditions. Achievement of regiospecificity and stopping the reaction at the desired stage is now possible in many cases.

Reagents of both inorganic and organic origin such as $FeCl_3$ (ref. 16), $K_3Fe(CN)_6$ (ref. 17), $AgOH$ (ref. 18), $K_2Cr_2O_7$ (ref. 19), $KMnO_4$ and K_2MnO_4 (ref. 20), iodobenzene diacetate²¹, active MnO_2 (ref. 22), manganese tris acetylacetonate (MTA)²³, tert-butyl peroxide, isoamyl nitrite²⁴, $O_2/NaOH$ (ref. 18), RuO_2 (ref. 25) and enzymes²⁶ have been used for this purpose. Irradiation by ultrasound in the presence of an oxidizing agent²⁷ has also been an efficient method for product formation. Solid-supported reagents such as Ag_2CO_3 on celite²⁸, $FeCl_3$ bound to SiO_2 (ref. 29), phosphomolybdic acid adsorbed on silica gel¹¹ also proved to be efficient reagents for the phenol coupling process. These special types of reagents are responsible for easier handling, separation procedures and higher efficiency. Anodic oxidations and oxidation via photochemical radical generation³⁰ are also viable methods for the OPC reaction. However, anodic oxidation may lead to solvent incorporation³¹, and with MTA, abnormal products may result³². Use of $AgNO_3$ (ref. 33) and chromyl chloride³⁴ may cause nitro and chloride group insertion. Sometimes the OPC reaction causes formation of phenyl ethers³⁵. Sometimes an attack at the benzylic position competes with the desired coupling process. Also, sometimes, OPC reaction results in quinones³⁶ or coupled quinone³⁷. A general theory has not been set up governing the formation of product; but variation of reagent and condi-

Scheme 3.

tion may lead to different products (Scheme 3) and sometimes isolated examples appear in the literature showing excellent yield. Reaction with another class of reagents including VOF_3 , $VOCl_3$, VCl_4 , thallium(III) tris trifluoroacetate (TTFA) may result in a 'non-phenolic' dehydrodimerization of electron-rich aromatic compounds³⁸.

An examination of the standard reduction potential (E^0) values for most of the reagents suggests that a reagent with lower E^0 value would behave in a milder way and cause less polymerization. This has been accomplished using Ag-gelatin complex³⁹, a weaker oxidizing agent than $AgOH$ or $AgNO_3$. Based on the E^0 values, uranyl(VI), rhodium(III), platinum(IV), and Hg(II) complexes would be expected to react similarly as reagents in the OPC reaction. One such observation on the OPC reaction is the coupling of 2,7-dihydroxy naphthalene by HgO (ref. 40).

Radical-initiated OPC to form polycyclic dimers and trimers has been observed using natural montmorillonite and smectic clays⁴¹ with favoured regio- and stereochemical control. The influence of steric, electronic and also hydrophobic character of the substrates has been documented with biocatalyst⁴² in nonaqueous solvent. Even now, newer inorganic reagents^{43,44} are being considered for successful coupling reaction. The underlying but obligatory condition is to impose milder conditions⁴⁵ to warrant better coupling instead of quinone formation. Thus macrocyclic chelates⁴⁶ and catalyst⁴⁷ have been employed. To achieve success, alteration of reaction conditions, purging of oxidizing gas have also been looked into. Stepwise coupling⁴⁸ has recently widened the horizon of OPC reaction to the greatest extent in relation to selectivity, complex-induced proximity effect, regiochemical control and percent yield conversion point of view.

Mechanistically it is believed that the first step in OPC is the generation of a phenoxy radical by the transfer of an electron to the oxidant as evidenced from the e.s.r. studies. The generated phenoxy radical then is thought to undergo a mostly homolytic coupling (Scheme 4). In extreme cases an ionic mechanism may also operate. While this mechanistic aspect has been

enlightened, more extensive work is necessary for understanding the precise mechanism of the entire reaction and there is no warranty that all phenol couplings proceed by one and the same mechanism¹.

In view of the many-fold applications of OPC reaction, one may think aloud about constructing bi- and polyaryls in a viable and efficient route. Apart from mimicking nature, this coupling process may be a passport for entering into the world of macrocycles⁴⁸. It is quite probable that this synthetic method may be accomplished by various means and is amply described in literature.

ACKNOWLEDGEMENT. We thank K. Houck for her invaluable suggestions and encouragement.

Received 5 February 1996; revised accepted 23 May 1996.

A symposium on 'High Energy Physics in the 21st Century' was held on 11 November 1995 at the Indira Gandhi Centre for Atomic Research, Kalpakkam as a part of the 61st Annual Meeting of the Indian Academy of Sciences, 10–12 November 1995 at Madras. The four themes of the symposium were: *The Standard Model of High Energy Physics, Theoretical Scenarios for 10^3 GeV to 10^{19} GeV, Hints of New Physics from Cosmology, Astrophysics and Nonaccelerator Experiments, and New Ideas on Acceleration to Planckian Energies.* Talks bearing on these themes were given by D. P. Roy, Romesh Kaul, Ramanath Cowsik and Abhijit Sen respectively. Three of these talks along with an introductory overview (by GR) and a final summary (by RR) which were also given in the Symposium are included in the following collection.

R. Ramachandran

High Energy Physics in the 21st century – An overview

G. Rajasekaran

Institute of Mathematical Sciences, Madras 600 113, India

At the beginning of the 20th century, the quest for the understanding of the atom topped the agenda of fundamental physics. This quest successively led to the unravelling of the atomic nucleus and then to the so-called 'elementary' particles – proton, neutron, pion, electron, etc. Particle Physics or High Energy Physics (HEP) made rapid strides in the latter part of this century, especially in the 60s and 70s. These developments culminated in the construction of the gauge theory of quarks and leptons. This theory which goes by the rather prosaic name of 'The Standard Model (SM) of High Energy Physics' was constructed almost in its final form by 1973 and since then it has passed with flying colours all the experimental tests performed in the next 20 years. So, at the end of the century, we now have a highly successful theory which is valid, down to a distance scale of about 10^{-16} cm (8 orders of magnitude smaller than the atomic scale). This theory can now be regarded as *the basis of all of physics except gravity*. This success story is described in the article on page 111 by D. P. Roy.

1900 A.D. —————→ 2000 A.D.
Atoms → Nuclei → Particles → Gauge theory of quarks
and leptons
——————————→
 10^{-8} cm 10^{-16} cm

The SM is a theory for all that is known in HEP, namely the weak, electromagnetic and strong interactions of the quarks and leptons. However, this is not the end of the story. There are too many loopholes and unsolved problems within SM: Higgs and symmetry breaking, QCD and confinement, neutrinos, CP and its violation, etc. The solution of these problems may already take us beyond SM.

However, the biggest loophole in SM is the omission of gravitation, the most important force of nature. Hence, it is now recognized that *Quantum Gravity (QG) is the next frontier of HEP*, and that *the true fundamental scale of physics is the Planck energy 10^{19} GeV*, which is the scale of QG.

In quantum mechanics, there is an inverse relationship between the length scale and the energy needed to probe that scale. A few characteristic length and energy scales are given below:

Landmark	Length	Energy
Nuclear physics	10^{-13} cm	200 MeV
Standard model	2×10^{-16} cm	100 GeV
↓	↓	↓
Quantum gravity	2×10^{-33} cm	10^{19} GeV

One can see the vastness of the domain one has to cover before QG is incorporated into physics. In their attempts to probe this domain of $10^2 - 10^{19}$ GeV, theoretical physicists have invented many ideas such as supersymmetry, supergravity, hidden dimensions, etc and based on these ideas, they have constructed many beautiful theories, the best among them being the superstring theory, which may turn out to be the correct theory of QG. These 'Theoretical scenarios for 10^3 GeV to 10^{19} GeV' is the topic of Romesh Kaul's article (page 116).

But, physics is not theory alone. Even beautiful theories have to be confronted with experiments and either confirmed or thrown out. Here we encounter a serious crisis facing HEP. In the next 10–15 years, new accelerator facilities with higher energies such as the Large Hadron Collider ($\sim 10^4$ GeV) or the Linear Electron Collider will be built and so the prospects for HEP in the immediate future appear to be bright. Beyond that period, the accelerator route seems to be closed because known acceleration methods cannot take us beyond about 10^5 GeV. It is here that one turns to 'Hints of new physics from cosmology, astrophysics and nonaccelerator experiments'. This topic was covered by Ramanath Cowsik in the Symposium. (Unfortunately, his talk could not be included in the present collection.)

Very important hints about neutrinos, dark matter, etc. have come from Astrophysics and Cosmology. Nonaccelerator experiments on proton decay, neutrino masses, double beta decay and 5th force are important since they provide us with indirect windows on superhigh energy scales.

In spite of the importance of astroparticle physics and nonaccelerator experiments, these must be regarded as only our first and preliminary attack on the unknown frontier. *These are only hints!* Physicists cannot remain satisfied with hints and indirect attacks on the superhigh energy frontier. *So, what do we do?*

As already mentioned, the outlook is bleak, because known acceleration methods cannot take us far.

To sum up the situation, there are many interesting fundamental theories taking us to the Planck scale and even beyond, but unless the experimental barrier is crossed, these will remain only as metaphysical theories.

It follows that either, *new ideas of acceleration have to be discovered* or, *there will be an end to HEP by about 2010 A.D.*

It is obvious what route physicists must follow. Hence, we have the very important article – 'New ideas on acceleration to Planckian energies' by Abhijit Sen (page 121). Some of the ideas being pursued are laser beat-wave method, plasma wake field accelerator, laser-driven grating linac, inverse free electron laser, inverse Cerenkov acceleration, etc. What we need are a hundred crazy ideas. Maybe, one of them will work. Lawrence's discovery of the cyclotron principle is not the end of the road. Here lies an opportunity of discovery our country should not miss.

A task force for new methods of particle-acceleration

It is high time that we form a small group of people as the task force whose aim shall be to do research and discover new methods of acceleration. This should be a multidisciplinary team including laser, plasma and accelerator specialists. It must include particle-detector specialists also, since the success of this venture will ultimately depend on our mastery of not only new methods of particle-acceleration but also new methods of particle-detection. One or two theorists with bright ideas may play a useful role in this group.

What is contemplated is *not* a new Institute or a new Department in any existing institute, but rather a think-tank of young people in existing institutions who are prepared to commit a significant part of the next 25 years of their careers to this visionary dream of creating a Planckian accelerator in the laboratory. These must be people with their eyes and minds turned on the heavens but with their feet placed securely on the earth and their hands actively engaged in the laboratory. They must be visionaries prepared to gamble on crazy ideas, but at the same time, having the capacity to test the ideas in down-to-earth laboratories *in this country*.

One must guard against big expenditure of money; the emphasis must rather be on investing on ideas. Clearly, what is expressed above is only the sketch of a proposal. Much more thought is required, to carry it forward to the practical stage. Hopefully, if the seed is planted now, it may grow and fructify in the next 25 years.

Finally, we must face the question: why should we do High Energy Physics? The answer can be given in the form of the following questions.

Is quantum mechanics for ever? Is relativity for ever?

Classical physics failed to explain the stability of the atom and thus quantum mechanics was born. Quantum gravity suggests that quantum mechanics may fail to explain the stability of space-time and so a new form of mechanics may be necessary. Such new discoveries may come only through the study of deeper regions of space-time. From this point of view, the onward march to shorter distances (higher energies) assumes a great significance. *Ultimately, the real justification for pushing the frontier of HEP to higher energies is the expectation that we will reach the boundaries of validity of our present view of the physical universe – based on our present conceptual framework of space-time (relativity) and our present understanding of dynamics (quantum mechanics) and that the new discoveries will take us beyond those boundaries.*

The standard model of fundamental particles

D. P. Roy

Theoretical Physics Group, Tata Institute of Fundamental Research, Homi Bhabha Road, Colaba, Bombay 400 005, India

This is an overview of our current understanding of the fundamental particles and their interactions, which is commonly called the Standard Model. The major developments in this field are outlined along with the major issues that remain to be settled. Important Indian contributions to these developments are underlined.

OUR concept of fundamental particles has undergone two revolutionary changes during this century. The first was the Rutherford scattering experiment of 1911 bombarding α particles on gold atom; while most of them passed through straight, occasionally, a few were found to scatter off at a large angle. This showed that the atom is not a solid compact object, but is largely hollow with a solid compact nucleus (made up of protons and neutrons) surrounded by the tiny revolving electrons. The second was the electron-proton scattering experiment of 1968 at Stanford, which was essentially a repeat of the Rutherford scattering type experiment, but at a much higher energy. The result was also very similar as illustrated in Figure 1. It was again clear from the scattering pattern that the proton is not a solid compact object itself, but is largely hollow with three solid compact cores called quarks. Indeed we know now from many such experiments, that all the nuclear particles (proton, neutron and mesons) are made up of quarks, i.e. they are quark atoms.

The reason it takes a much higher beam energy to probe the structure of the nuclear particles is their small size relative to the atom, about 1 fm (10^{-15} m) against 1 Å (10^{-10} m). It follows from the famous Uncertainty Principle that the uncertainties in distance and energy are related by

$$\Delta x \Delta E > \hbar c \sim 0.2 \text{ GeV} \cdot \text{fm}, \quad (1)$$

i.e. probing a distance scale $x \ll 1$ fm requires a beam energy $E \gg 1$ GeV, where a Giga electron volt ($\text{GeV} = 10^9 \text{ eV}$) is the energy acquired by an electron on passing through a billion volts. It is this multi-billion volt accelerator technology that is responsible for the half a century gap between the two experiments. The Stanford experiment got the Nobel Prize in 1990.

In particle physics one normally uses the so-called natural units

$$\hbar = c = 1, \text{ i.e. } m = mc^2. \quad (2)$$

That means the mass of a particle is same as its rest mass energy. The GeV is the most commonly used unit of mass, energy and momentum. The mass of proton $m_p \simeq 1 \text{ GeV}$.

Basic constituents of matter

According to our present understanding the basic constituents of matter are a dozen of spin-1/2 particles (fermions) along with their antiparticles. These are the 6 leptons (electron, muon, tau and their associated neutrinos) and the 6 quarks (up, down, strange, charm, bottom and top). Each can be organized into 3 pairs, in increasing order of mass (Table 1). Members of each pair differ by 1 unit of electric charge as shown in the last column, i.e., charge 0 and -1 for the neutrinos and the charged leptons and $2/3$ and $-1/3$ for the upper and lower quarks. This is relevant for their weak interaction. Apart from the electric charge the quarks possess a new kind of charge called colour charge. This is relevant for their strong interaction, which binds them together inside the nuclear particles (hadrons).

Basic interactions

There are 4 basic interactions among these particles – strong, electromagnetic, weak and gravitational. Apart

Table 1. Basic constituents of matter

Leptons	ν_e	ν_μ	ν_τ	0
	e	μ	τ	-1
Quarks	u	c	t	$2/3$
	d	s	b	$-1/3$

ν , neutrino; u , up quark; d , down quark; c , charm quark; t , top quark; s , strange quark; b , bottom quark.

Table 2. Basic interactions

Interaction	Strong	EM	Weak
Carrier	g	γ	W^\pm & Z^0
		$U(1)$	$SU(2)$
Gauge group	$SU(3)$	$SU(2) \times U(1)$	

g , gluon; γ , photon; W , charged weak boson; Z , neutral weak boson.

SPECIAL SECTION – HIGH ENERGY PHYSICS

from gravity, which is too weak to have any perceptible effect in particle physics, the other three are all gauge interactions. They are all mediated by spin-1 (vector) particles called gauge bosons, whose interactions are completely specified by the corresponding gauge groups (Table 2).

The three basic interactions are illustrated by Feynman diagrams shown in Figure 2. They are simple space-time pictures, where the arrows indicate the direction of time. It may be noted here that a particle line is equivalent to the corresponding antiparticle with the direction of the time arrow reversed. Thus the same Feynman diagram represents the scattering process

$$(a) \, qq \rightarrow qq, \quad (b) \, q\bar{q} \rightarrow q\bar{q}, \quad (c) \, d\nu_e \rightarrow u\bar{e}, \quad (3)$$

as well as the corresponding annihilation process

$$(a) \, q\bar{q} \rightarrow q\bar{q}, \quad (b) \, \ell\bar{\ell} \rightarrow q\bar{q}, \quad (c) \, d\bar{u} \rightarrow e^-\bar{\nu}_e, \quad (4)$$

where the bar denotes the antiparticle. The last diagram also represents the decay process

$$\mu^- \rightarrow \nu_\mu e^- \bar{\nu}_e \text{ or } d \rightarrow u e^- \bar{\nu}_e, \quad (5)$$

the latter being responsible for neutron decay. The rate of the scattering, annihilation or decay is simply given by the square of the corresponding Feynman amplitude given below each diagram, where Q^2 denotes the 4-momentum square transferred.

The quarks interact strongly by the exchange of a massless vector particle called gluon, whose couplings are proportional to their colour charge C (Figure 2a). This is analogous to the electromagnetic interaction between quarks and charged leptons by the exchange of the massless photon, whose couplings are proportional to their electric charge e (Figure 2b). The constant of proportionality for the strong interaction is called α_s in analogy with the fine structure constant α ($\simeq 1/137$) for the electromagnetic interaction. And in analogy with Quantum Electro-Dynamics the theory of strong interaction is called Quantum Chromo-Dynamics (QCD). There is an important distinction between the two interactions, however, which follows from the non-abelian nature of the strong interaction gauge group $SU(3)$. Unlike the photon which does not carry electric charge, the

Figure 1. The Stanford electron-proton scattering experiment.

Figure 2. Feynman diagrams for (a) strong, (b) electromagnetic and (c) weak processes.

gluon carries a colour charge and hence has self-interaction. This is responsible for the most distinctive property of strong interaction called confinement, i.e. the quarks and gluons are perpetually confined inside the nuclear particles (hadrons); they cannot be pulled apart! The weak interaction between the quarks and leptons is mediated by massive vector particles called W^\pm and Z^0 bosons. The charged W boson couples to the above pairs of quarks and leptons with a universal coupling α_w (Figure 2c), since they all belong to the doublet representation of the weak gauge group $SU(2)$, i.e. they carry the same gauge charge. This is called the charged current weak interaction. The neutral Z boson couples to each quark and lepton, mediating the neutral current weak interaction, e.g.

$$q\nu \xrightarrow{Z} q\nu. \quad (6)$$

Electro-weak unification

The weak and the electromagnetic interactions have been successfully unified in terms of a $SU(2) \times U(1)$ gauge theory, for which Glashow, Salam and Weinberg were awarded the Nobel Prize in 1979. Being a product group it contains two independent gauge couplings, whose relative magnitude is defined in terms of a parameter called the weak mixing angle θ_w . The weak couplings α_w and α_z are related to the electromagnetic coupling α in terms of this parameter. Following the discovery of the neutral current weak interaction¹, the parameter θ_w was estimated² from the relative rates of the charged and neutral current weak interactions (3c) and (6). The present value of this parameter is

$$\sin^2 \theta_w \simeq 0.23. \quad (7)$$

Thus

$$\alpha_w = \alpha / \sin^2 \theta_w \simeq 4\alpha \simeq 1/30, \quad (8)$$

i.e. the weak coupling is in fact stronger than the electromagnetic. The rate of the weak process (Figure 2c) is weaker than the electromagnetic (Figure 2b) due to the

extra suppression factor coming from the large W mass. Note that this is only a low-energy phenomenon, occurring at $Q^2 \ll M_W^2$. The two rates are predicted to become comparable at $Q^2 \geq M_W^2$, as indeed they do. In other words the electro-weak unification takes place at the energy scale of the W boson mass. One can also predict the W boson mass from the observed rate of a low energy weak process like μ decay (Figure 2 c). One gets

$$M_W \simeq 80 \text{ GeV and } M_Z = M_W / \cos \theta_W \simeq 91 \text{ GeV,} \quad (9)$$

i.e. they are about 100 times heavier than the proton.

Discovery of the fundamental particles

The list of fundamental particles consists of the above-mentioned quarks, leptons and gauge bosons. The up and down quarks are the constituents of proton $p(uud)$ and neutron $n(udd)$. So together with the electron they constitute all the visible matter around us. The heavier quarks and leptons are unstable and hence not freely occurring in nature. But one can produce them in the laboratory experiments or detect them in the cosmic rays. The muon and the strange quark were discovered in cosmic ray experiments in the late forties, the latter in the form of the K -meson ($s\bar{d}$). The neutrinos are massless and stable, but hard to detect because of their weak interaction with matter. The ν_e was discovered in an atomic reactor experiment in the mid-fifties and awarded Nobel Prize this year (1995), while the ν_μ was detected at the Brookhaven proton accelerator in 1962 and awarded Nobel Prize in 1988. The first cosmic ray observation of neutrino (ν_μ) was made in the Kolar Gold Mine experiment in 1965 (ref. 3).

The remaining constituents of matter as well as the carriers of the basic forces have all been discovered during the last two decades, thanks mainly to the electron-positron and proton-antiproton colliders. In fact, over half of these discoveries were made during the seventies. The charm quark and the tau lepton were discovered at the Stanford e^+e^- collider in 1973 and 1975 respectively. The former got the Nobel Prize in 1976 and the latter got it this year (1995). The bottom quark was discovered at the Fermilab proton accelerator in 1977; but most of its detailed studies have been done at the e^+e^- colliders. The basic production mechanism is the electromagnetic annihilation process of (4b), where the kinetic energy of the colliding e^+e^- pair is converted into the rest mass energy of the produced particles ($m_c \simeq m_\tau \simeq 2 \text{ GeV}$, $m_b \simeq 5 \text{ GeV}$), (see Figure 3). At first the produced particles were recognized from the nature of their decay products. But it has been possible now to track them before their decay. The gluon was discovered at the Hamburg e^+e^- collider in 1979 in the form of 3-jet events. The basic production process is again the electromag-

Figure 3. The discoveries of charm, tau, bottom and gluon.

Figure 4. The discovery of W and Z bosons.

netic annihilation of e^+e^- into a quark-antiquark pair as in (4b), but followed by the QCD process of gluon radiation from one of the outgoing quarks.

One may ask how do these quarks and gluon come out of the confinement domain of $\sim 1 \text{ fm}$? The answer is that in quantum mechanics there can be many quarks and gluons floating in the vacuum, since their energy-momenta are taken care of by the Uncertainty Principle. Each of the produced particles picks up some extra quarks and gluons from the vacuum to come out as a colourless cluster of hadrons (mostly mesons). This results in an energetic jet of hadrons, carrying the energy and momentum of the produced particle. One expects only a small amount of momentum smearing, $\Delta p \sim 0.2 \text{ GeV}$, from the Uncertainty Principle (1).

The production of the massive W and Z bosons requires highly energetic beams, which was first achieved at the CERN $\bar{p}p$ collider (the $\bar{p}p$ collider has a higher energy reach than the e^+e^- machine, while the latter is better suited for detailed investigations). These particles were discovered there in 1983, which got the Nobel Prize the following year.

The underlying production mechanisms are the quark-antiquark annihilation process (4c) for W and the analogous neutral current process for Z (see Figure 4). Although the W and Z bosons decay instantly, they leave unambiguous imprints in their decay products as illustrated in the figure. One can easily infer about the production of W and Z bosons and measure their masses from these imprints. More recently millions of Z bosons have been produced at the Large Electron-Positron (LEP) collider at CERN resulting in a detailed study of the Z boson properties. The second phase of LEP, currently in progress, will produce W^+W^- pairs and make a detailed study of the W boson properties. An Indian group has been participating in

Figure 5. The discovery of the top quark.

one of the LEP experiments called L3, where it has made significant contributions to hardware, software as well as the data analysis. In particular, this group has been the main contributor to the line shape analysis of the Z boson signal⁴.

The last and the heaviest of these fundamental particles, the top quark, has been discovered this year (1995) at the Tevatron $\bar{p}p$ collider at Fermilab^{5,6}. Its mass is about 200 times larger than the proton mass, and, hence, it decays instantly like the W and Z bosons. But the characteristics of its decay products are far more complex. Figure 5 illustrates the production and decay of a top quark pair at the $\bar{p}p$ collider. The underlying mechanism for $\bar{t}t$ production is the QCD annihilation process of (4a), where the kinetic energy of the colliding $u\bar{u}$ is converted into the restmass energy of the $\bar{t}t$ pair. The decay mechanism is similar to that of (5).

One looks at the leptonic decay of one of the top quarks to avoid the QCD background from the scattering of stable quarks and gluons. The huge energy release in the decay of the massive top quarks implies that (i) the decay lepton (e or μ) comes out wide apart (isolated) from the other decay products and (ii) all the decay quark jets are hard, i.e. they carry large transverse-momenta. The first criterion helps to distinguish it from the b and c quark backgrounds and the second from the W boson background. The lepton isolation and jet hardness criteria for the top quark signature were first suggested in refs. 7 and 8 respectively. They have been widely used in the top quark search and its ultimate detection in the CDF⁵ and D0⁶ experiments at the Tevatron collider. Three Indian teams from Bombay, Chandigarh and Delhi are participating in the D0 experiment, where they have made significant contributions to the hardware and data analysis.

It is clear from the above discussion that particle physics has come a long way in the last 25–30 years. But the journey is far from over yet. There are several issues in strong and more importantly in weak interaction physics, which remain to be settled.

Confinement

We do not have a complete understanding of confinement yet, although there has been impressive progress in this direction in recent years. It has come in particular from the lattice gauge theory approach using large scale computer simulations, where Indian theorists have made notable contributions. A crucial prediction of this theory is the deconfinement of quarks and gluons into a quark-gluon plasma (QGP) in some extreme conditions, which may be achieved in relativistic heavy ion collision. Consequently, there is an extensive programme to search for QGP signal in the present and proposed heavy ion accelerators at CERN and Brookhaven. Experimental groups from Bhubaneswar, Calcutta, Chandigarh, Jaipur, Jammu and BARC (Bombay) are actively participating in this programme.

Mass problem: Higgs mechanism

The most serious problem of the Standard Model arises from the fact that the weak gauge bosons, W and Z, are massive. The gauge boson mass terms break the gauge symmetry of the Lagrangian, required for a renormalizable theory. The latter is essential for the cancellation of the infinities occurring in the theory. So the question is how to give mass to the weak gauge bosons without breaking the gauge symmetry of the Lagrangian? The clue is provided by the fact that spin-0 (scalar) particle masses are not constrained by any symmetry. This can be exploited to give mass to the gauge bosons through back door, i.e. they acquire mass by swallowing massive scalar particles. This is achieved via the Higgs mechanism of spontaneous symmetry breaking, which leaves the symmetry of the Lagrangian and hence the renormalizability of the theory intact. However it predicts at least one remaining scalar particle called Higgs boson in the mass range of W and Z bosons, which is yet to be detected.

Hierarchy problem: supersymmetry

Solving the mass problem via the Higgs mechanism leads to the so-called hierarchy problem, i.e. how to control the Higgs boson mass in the desired range of W and Z masses. This is because in the absence of a protecting symmetry the scalar masses have divergent quantum corrections, making them infinitely heavy. By

Figure 6. Divergent quantum correction to the Higgs boson mass coming from quark and lepton pairs (left) and its cancelling contribution coming from their superpartners (right).

far the most promising solution to this problem is provided by supersymmetry (SUSY), which is a basic symmetry between fermions and bosons, i.e. all fermions have bosonic superpartners and vice versa. It ensures cancellation⁹ between the divergent quantum corrections coming from the exchange of the standard particles and their superpartners as illustrated in Figure 6. In the process, however, one predicts a host of new particles, scalar partners of quarks and leptons as well as fermionic partners of gauge and Higgs bosons, to occur in the mass range of W and Z bosons. The two sets of particles are distinguished by a multiplicative quantum number called R -parity, which is $+1$ for all the standard particles and -1 for their superpartners. Conservation of R -parity implies that (i) the superparticles are produced in pair and (ii) the lightest superparticle (LSP) resulting from their decay is stable. The LSP is also required to have no colour or electric charge. Consequently, it is expected to interact weakly with matter and escape detection like the neutrino. This results in an apparent momentum imbalance (missing-momentum), which serves as a powerful signature for superparticle production. The first such signature for superparticle production at $\bar{p}p$ colliders was formulated by Reya and Roy¹⁰.

The Higgs and superparticles are the minimal set of missing pieces, required to complete the current picture of particle physics. It may not be the ultimate theory; but at least it will be a complete and self-consistent theory. As such the search for these particles are the prime physics goals of the present and proposed high energy colliders. In particular, the large hadron collider (LHC), scheduled to be completed in 2005 at CERN, will make it possible to carry the Higgs and superparticle searches right up to their predicted mass limits. An Indian team is actively participating in the R & D of one of the proposed experiments (CMS) at LHC, while several theorists are engaged in devising optimal search strategies for these particles at LHC using computer simulations. The observation of these particles will complete the current picture of particle physics in the way outlined above, while their nonobservation at LHC will provide important clues to an alternative route.

Theoretical scenarios for 10^3 GeV to 10^{19} GeV

Romesh K. Kaul

Institute of Mathematical Sciences, Taramani, Madras 600 113, India.

Basic dogmas of particle physics are reviewed. Some of their implications beyond the standard model are explored. Higgs sector of the standard model of electroweak interactions is the weakest link in the model. Elementary Higgs field makes the model 'unnatural' beyond about 10^3 GeV. Supersymmetry provides the most attractive framework wherein this problem can be addressed. This new symmetry, relating fermions and bosons, is expected to be operative at about 10^3 GeV. In addition, grand unification of the fundamental interactions can be studied consistently only within a supersymmetric formulation. Inclusion of gravity with other interactions leads to supergravity theories, which should emerge as a low energy description of a more fundamental theory, the string-theory. Supersymmetry again is an essential feature of such a theory. Quantum gravity, with its characteristic scale of 10^{19} GeV, may well be described by a superstring theory.

TODAY, particle physics involves six quarks and six leptons as the fundamental constituents of all matter. It was only last year that the sixth quark, the 'top', was discovered. The quarks come in three-somes, the three colours. The quarks and leptons experience four types of basic forces, electromagnetic, weak nuclear, strong nuclear and gravitational. The electromagnetic and weak forces are described by the model of Glashow, Salam and Weinberg¹⁻³, while the strong interactions experienced by the quarks are believed to be governed by Quantum Chromodynamics (QCD). These together form the Standard Model of particle physics. Einstein's general theory of relativity provides an excellent description of the gravitational forces at large distances. However, short distance picture of gravity, where quantum effects become relevant is still puzzling. In this sense, quantum gravity is the least understood of all the basic forces of Nature.

The present theoretical understanding of the fundamental constituents and the forces experienced by them is governed by four guiding principles or dogmas: (i) Gauge principle, (ii) Renormalizability (or finiteness for theories with gravity), (iii) Naturalness principle, and (iv) Unification of the fundamental forces of Nature. We shall review these ideas in the following.

Gauge dogma

Every fundamental force has an underlying gauge principle. The oldest known gauge principle is that of electromagnetic interaction. The physical consequence of this principle is that this force is carried by a spin one massless vector gauge quantum, the photon, with an underlying gauge group $U(1)$. Two other fundamental interactions, the weak and strong nuclear forces are also governed by gauge theories. In the successful unified picture of electromagnetic and weak interactions due to Glashow, Salam and Weinberg¹⁻³, we have a gauge theory of four spin 1 gauge quanta. One of these is massless and is identified with the photon. Other three are massive, two charged W_{μ}^{\pm} and one neutral Z_{μ}^0 . These mediate weak nuclear forces. The underlying gauge group of this theory is $SU_L(2) \times U_Y(1)$ which is spontaneously broken down to an electromagnetic $U(1)$. Discovery of these gauge bosons, W^{\pm} and Z^0 in 1983, a major event in the history of science, confirmed the now thirty-year-old electroweak theory.

The strong nuclear force which holds the quarks together in a proton or neutron is described in terms of eight spin one gauge bosons, the gluons, corresponding to a gauge theory based on colour group $SU_C(3)$.

The gravitational interaction, usually thought of in terms of geometric properties of space-time, is also compatible with the gauge dogma^{4,5}. This force is mediated by a postulated spin two massless field, the graviton. Experimental discovery of this gauge particle is an outstanding problem. Whereas non-gravitational forces are described by the gauge theories of internal symmetry groups, the gravitational interaction is governed by the gauge theory of space-time symmetries. In this sense gravity is somewhat different.

Principle of renormalizability

All the known non-gravitational fundamental forces of nature are described by renormalizable quantum gauge field theories. These theories combine the building blocks of modern physics, special theory of relativity, quantum and gauge principles. Quantum field theories are generically plagued with infinities. In renormalizable field theories, there is a systematic way of absorbing

these infinities into redefinition of the fields and parameters, leaving behind only finite values for them. Unfortunately, this is not true for quantum theory of gravity. The root of the problem is that, unlike other quantum gauge field theories, description of gravity necessarily, involves a dimensionful coupling constant, Newton's gravitational constant. This makes one-loop or higher divergences in this theory to have a functional form other than that of the quantum action. Therefore, the usual prescription of absorbing these infinities back into the original quantum action by rescaling the parameters and fields is not available. In fact the gravitational quantum field theories may in general never be perturbatively renormalizable.

There are only two extreme options for the gravitational field theories: either the infinities of the S -matrix cannot be removed at all, or the infinities on their own are altogether absent. Thus, an acceptable quantum theory of gravity should be finite on its own – there should be some inner mechanism such that the divergences cancel. Some symmetry may provide such a mechanism. Obviously, finiteness of the S -matrix is a stronger constraint than renormalizability. But, it appears that quantum gravity has to choose a more miraculous way of existing other than the soft option of renormalizability that other interactions adopt.

Naturalness dogma

According to this dogma, existence of a small parameter in Nature cannot be an accident, there must be an associated symmetry. This is best formulated as follows:

't Hooft's doctrine of naturalness: At any energy scale μ , a set of physical parameters, $\alpha_i(\mu)$ may be small, if and only if in the limit $\alpha_i(\mu) \rightarrow 0$, the system has an enhanced symmetry⁶.

The weakly broken symmetry ensures that the smallness of the parameter is stable against perturbative influences. An example of a perfectly natural theory is quantum electrodynamics. The electromagnetic coupling α , the electron mass m_e , the muon mass m_μ , etc. can all be independently small. The smallness of m_e (or m_μ) is protected by the fact that, in the limit $m_e \rightarrow 0$ (or $m_\mu \rightarrow 0$), we have an additional symmetry corresponding to the separate conservation of the left- and right-handed electron-like leptons. All corrections to the electron mass due to the quantum fluctuations are small, proportional to m_e itself. Also, $\alpha \rightarrow 0$ enhances symmetry; it implies no interaction; hence the particle number of each type is conserved.

On the other hand, field theories with elementary scalar fields are not natural. There is no approximate sym-

metry that protects the smallness of the scalar mass. Electroweak theory has an elementary scalar field in its Higgs sector. This provides masses to the weak gauge bosons W^\pm , Z^0 through the so-called Higgs mechanism breaking the electroweak gauge group $SU(2) \times U(1)$ to the electromagnetic $U(1)$ at about 100 GeV. This ensures the renormalizability of such a theory of massive non-abelian gauge bosons. Though Higgs particle is central to our present understanding of structure of matter, yet it has stayed completely elusive. Experimental discovery of this particle is a major outstanding problem of present times. That is why Leon Lederman has nicknamed it as 'the God Particle'⁷. Being an essential part of the standard model, at the same time it renders the electroweak theory 'unnatural'. That is, the 100 GeV scale of this theory is no longer stable under perturbative quantum corrections. For definiteness, the correction to Higgs mass m_H due to quantum fluctuations of a size characterized by a scale Λ is

$$\delta m_H^2 \propto \alpha \Lambda^2,$$

say, at one loop level. Corrections to the masses of weak gauge bosons W^\pm and Z^0 are also of the same order. This is because these gauge bosons acquire masses through spontaneous symmetry breaking whose scale is controlled by the Higgs mass. Thus, if $m_H \sim 100$ GeV, and $\alpha \sim \frac{1}{100}$, and if we wish that the Higgs mass does not receive large corrections, $\delta m_H \sim m_H$, we have:

$$\Lambda^2 \sim \frac{\delta m_H^2}{\alpha} = \frac{(100 \text{ GeV})^2}{1/100} = (1000 \text{ GeV})^2$$

$$\Lambda \sim 10^3 \text{ GeV} = 1 \text{ TeV}.$$

Naturalness of the electroweak theory breaks down at this scale. If there were no new mass scales, or equivalently no new physics beyond 1 TeV, there was no problem. But that is not so. In general there is no reason to believe that there is no new heavy particle, or new interaction with characteristic scales $> 0(1)$ TeV. In particular, we already know, there is a physical scale, 10^{19} GeV associated with quantum gravity. Thus, natural scale of the electroweak theory, as it stands today, is not 100 GeV but 10^{19} GeV! It is an immediate and serious problem. However, what this hints at is only that there has to be some new physics at and beyond 10^3 GeV so that the standard model with its characteristic scale of 100 GeV becomes natural.

One framework for addressing this problem is to think of the scalar Higgs, not as an elementary particle but, as a fermion-antifermion composite, much in the same way as a pion is made of a quark and an antiquark. This is what is called the technicolour option⁸⁻¹¹. Technicolour is the name given to the new postulated QCD-type force, again a gauge interaction, that would keep these new fermions, techniquarks together in the Higgs particle.

Thus, if we were to probe the Higgs particle with energies greater than 10^3 GeV, we would see it not as an elementary scalar particle, but as a techniquark and a techni-antiquark. Since theories with only fermions and gauge fields are natural like the electrodynamics, now there is no naturalness problem. The condensation of techniquarks results in the masses for weak gauge bosons W^\pm and Z^0 . This still does not solve the problem of masses for the quark and lepton. For that a new gauge interaction, the extended technicolour is introduced. The extended technicolour gauge bosons with masses of the order of 10–100 TeV connect the ordinary quarks and leptons with the techniquarks. This provides a mechanism for the masses of quarks and leptons. However, there are some serious phenomenological difficulties with this scenario. The difficulties include the non-observation of large flavour changing neutral current effects, heavier Higgs particle, absence of large anomalous contributions to the $Zb\bar{b}$ vertex and large contributions to S , T and U parameters^{10–12}.

Another perhaps more attractive framework for addressing the naturalness problem of the electroweak theory is supersymmetric^{13–17}. This option retains the elementarity of the scalar field. In a supersymmetric theory, the naturalness violating effects due to bosonic and fermionic quantum fluctuations cancel against each other. Since this cancellation has to operate at all orders of perturbation, we need a symmetry which relates the bosonic effects to fermionic effects. That is what supersymmetry does: it relates bosonic and fermionic degrees of freedom.

Supersymmetry^{18–20} requires that bosons and fermions come in families. For example, the photon has a superpartner, a neutral fermion, the photino; the electron is accompanied by a scalar partner, the selectron; quarks have scalar partners, squarks; the weak gauge bosons, W^\pm and Z have fermionic partners, the wino and zino, etc. Similarly, if we are studying gravity, spin 2 graviton has a superpartner, a spin 3/2 fermion, so-called gravitino.

Exact supersymmetry would imply that all the properties except the spin of particles in a supermultiplet are the same. Thus, the masses and couplings of superpartners would be exactly equal. This, however, is not borne out in Nature, otherwise we would have already seen, say, the selectron, a scalar electron with the same mass and charge as the electron. Hence supersymmetry must be broken so that the superpartners are heavy enough to have been beyond any detection so far. This breakdown should be such that the basic reason for introducing supersymmetry, namely the naturalness problem, does not get out of hand again. In fact the cancellation between the bosonic and fermionic quantum fluctuations need not be exact, it should be only up to the naturalness breakdown scale of the standard model:

$$m_{\text{particle}}^2 - m_{\text{particle}}^2 \leq (10^3 \text{ GeV})^2.$$

Thus what is required is only a TeV scale supersymmetry. Then, the masses of the particles would be less than one TeV. Present and next generation colliders may, therefore, be able to discover supersymmetry.

The minimal supersymmetric extension of the standard model consists of adding supersymmetric partners to the field content of the standard model. For anomaly-free extension, it also contains two Higgs doublets instead of one. All renormalizable supersymmetric interactions consistent with various global conservation properties are included. In addition, the most general soft-supersymmetry breaking terms (with mass parameters associated with them of the order 1 TeV or below to meet the naturalness constraint) are added.

Besides, the compelling naturalness arguments developed in early eighties^{13–17}, there are other reasons that have emerged since then in support of supersymmetry^{12,21}. Some of these are:

(i) Phenomenologically, a major development hinting at supersymmetry is the beautiful quantitative agreement of precision measurements of the low-energy electroweak coupling constants with the predictions of supersymmetric unified theories. Non-supersymmetric alternative extensions of the standard model have difficulties in this regard.

(ii) Unification of electroweak and strong nuclear forces is possible only in supersymmetric framework; the three coupling constants tend to meet in a point as we go up in the energy scale only in the minimally supersymmetric standard model. We shall return to this point again later.

(iii) There are cosmological implications of supersymmetry. For example, in the minimal supersymmetric standard model, there is a light supersymmetric particle (LSP) which has qualitatively neutrino-like properties. This would be a satisfactory candidate for cold dark matter.

These positive hints are surely tantalizing. Are these mere coincidences? Are there somewhat more definite ways in which we would know if TeV scale supersymmetry is indeed relevant or otherwise? Two possible ways are:

(a) As mentioned above, in supersymmetric extensions of the standard model, there are more than one Higgs doublet. For the lightest Higgs particle, there are rigorous upper bounds, independent of the detailed assumptions, in these models. This is not so in the non-supersymmetric standard model. The numerical value for this bound in minimal supersymmetric standard model is about 150 GeV. For more complicated models (with broken R -parity), this value may go up to 175 GeV. Thus, if no Higgs particle is seen experimentally up to about this upper limit, it is a signal that TeV supersymmetry may not be operative in Nature.

(b) Minimal supersymmetric extension generically tends to reduce the value of quantum corrected parameters, such as couplings, towards the classical (tree) values as compared to those in the non-supersymmetric theory. This is due to the approximate Bose–Fermi cancellations in the loop effects. Thus, in the more detailed experimental precision tests, if the values of the low energy electroweak couplings tend to deviate systematically from the non-supersymmetric theoretical values towards the tree values, this would be a strong hint of minimal supersymmetry.

In the end, only experimental discovery of the superpartners will be the complete vindication of the supersymmetric ideas.

Unification dogma

The oldest example of unification is Maxwell's theory of electromagnetism which provides a combined description of electricity and magnetism. $SU_L(2) \times U_Y(1)$ electroweak theory is a mixed theory of electromagnetic and weak forces. There have been various attempts at developing unified theories of electroweak forces and strong nuclear forces^{22,23}. The most popular one is where three groups of the standard model, $SU_C(3) \times SU_L(2) \times U_Y(1)$ are embedded in a larger group, $SU(5)$. All these attempts at grand unifications imply new mass scales much above 1 TeV. As we have argued earlier, mass scales above 1 TeV make the standard model scale perturbatively unstable. It is, therefore, clear that the unification of these three basic forces can be achieved consistently only in a supersymmetric framework. Further, as alluded to earlier, there is a remarkable property associated with the running coupling constants of the minimal supersymmetric extension of the standard model. The three coupling constants $\alpha_1, \alpha_2, \alpha_3$ associated with the gauge groups $U(1) \times SU(2) \times SU(3)$ respectively evolve with the energy in such a way as to meet at a point only in the minimal supersymmetric standard model and not in the non-supersymmetric standard model²⁴. The meeting point occurs at $\mu = 2 \times 10^{16}$ GeV. It is a clear hint of unification at about 10^{16} GeV in the supersymmetric case. Above this scale, all the three interactions are the same and are governed by a single coupling constant corresponding to gauge group $SU(5)$.

In this $SU(5)$ unification, the quarks and leptons are members of one family. The differences which are seen between quarks and leptons are to be viewed as the low-energy phenomena obtained by spontaneous breakdown of the larger $SU(5)$ symmetry to the smaller $U(1) \times SU(2) \times SU(3)$ symmetry at the unification scale of about 10^{16} GeV. In this scenario, there are gauge interactions between the quarks and leptons me-

diated by new gauge fields, the lepto-quark gauge bosons of $SU(5)$. These new gauge bosons are very heavy, with masses given by the unification scale with the result that the new interactions are very weak. One important implication of these new interactions is that proton in these models is not completely stable. Its lifetime is large but finite, $\tau_{\text{susy}} \sim 10^{35} - 10^{39}$ years in the supersymmetric $SU(5)$ theory, as compared to $\tau_{\text{non-susy}} \sim 10^{27} - 10^{31}$ years in the nonsupersymmetric $SU(5)$ model. Experimental limits for proton lifetime are $\tau_{\text{expt}} > 10^{32}$ years, clearly in contradiction with non-supersymmetric model, but consistent with the supersymmetric version. This is satisfying from the supersymmetric point of view. It need not have been so. This surely is not evidence for supersymmetry, but, if the proton lifetime had not worked out to be long enough, it would have been a clear evidence against minimal supersymmetric $SU(5)$ unification.

The unification scale for the three interactions, the electromagnetic, weak and strong, $\mu \sim 10^{16}$ GeV is only three orders of magnitude away from the scale of quantum gravity, $\mu_{\text{Planck}} \sim 10^{19}$ GeV, at which the quantum features of gravity become relevant. It may as well be that we should be thinking of unification of all the forces, including gravity, at the same time. Here again supersymmetry offers an advantage. So far we had been discussing supersymmetry which holds in the same way everywhere in space-time, the global supersymmetry. We could also think of supersymmetry which holds independently at every point of space-time, the so-called local supersymmetry. Gravity is automatically included in such theories. These theories are called supergravity theories. Here spin 2 transverse graviton has a partner, spin 3/2 gravitino. Supersymmetric matter can also be added to these theories. Recall we want a good quantum theory of gravity to be finite. Unfortunately, supergravity theories still are not satisfactory from this point of view. Thus we can think of supergravity theories only as effective low energy theories. As we go up in the energy scale up to the Planck scale, the supergravity theories would have to be replaced by some other fundamental theory which would have to be finite. There do exist candidates for such a theory. These are the superstring theories.

In a string theory²⁵, the elementary entities are not point particles, but tiny linearly extended objects of the size of Planck length, 10^{-33} cm. Strings can be of two types: open strings and closed strings. Ordinary matter like electrons, quarks, photon, gluons, etc. and their superpartners are described by an open superstring. Graviton and its superpartner gravitino are identified with a closed superstring. This identification respects the basic interaction properties of these particles, namely all types of matter experience the gravitational forces, but graviton does not experience the non-gravitational forces. This property is reflected in the fact

Figure 1a, b. An open string emits an open string and a closed string but a closed string emits only closed strings.

that an open string can emit a closed string as in Figure 1a, but a closed string can emit only a closed string, not an open string, as in Figure 1b.

This picture is indeed encouraging. In fact it does turn out that a closed string does have a spin 2 massless excitation to be identified as the transverse graviton, and open string does have massless spin 1 excitations which are identified with transverse vector gauge bosons.

Some of the features of the string theories are²⁵:

(i) This is a framework where all the fundamental forces, including gravity, are unified. It also unifies the matter (quarks and leptons) with mediators of the basic forces (gauge fields), as all these are supposed to be excitations of the same string. That is why sometimes, the string theory is pompously advertised as the *Theory of Everything*.

(ii) Superstring theory provides a *consistent* and *finite* theory of quantum gravity. It is for the first time that principles of general theory of relativity and quantum physics have been consistently married.

(iii) Even if, in the end, it does not turn out to be a completely satisfactory description of Nature, it does provide a theoretically rich testing ground for important conceptual issues of quantum gravity, particularly those related to the fate of black holes.

(iv) Supersymmetry is essential for this theory. Without supersymmetry, string theory is not consistent; it has a tachyon in its spectrum and also it does not provide a finite theory of gravity.

The superstring theory is also beset with difficulties. One problem is that there are several versions of the theory with no clear indication at present as to which of them is preferred by Nature. There is no understanding of the mechanism of supersymmetry breaking both in the supersymmetric field theories as well as in the superstring theories. These issues are expected to be related to the non-perturbative behaviour of these theories. There have been some recent developments which have allowed significant progress in this direction. A lot of circumstantial evidence is emerging for an electric-magnetic type of duality in these theories which relates any string theory at strong coupling to another string theory at weak coupling²⁶⁻²⁸. This may point towards the fact that there is only one fundamental theory of which the various superstring theories are only the asymptotic limits.

Though superstring theory provides a rich and conceptually deep framework, a major difficulty with it is that there is at present no easy way to test whether it is a correct description of Nature. Experimentally-useful effects of strings would occur typically at 10^{19} GeV. There is a huge gap between the present and near future experimentally reachable energy of 10^3 GeV and the Planck scale of 10^{19} GeV where the stringy features manifest. How can this gap be bridged or substantially narrowed?

Summary

We have explored the four dogmas of theoretical high energy physics, namely gauge principle, renormalizability (or finiteness for gravity), naturalness and unification. The requirement that the standard model be natural beyond 1 TeV leads to the extraordinary conclusion that Nature should be supersymmetric at that scale. This is experimentally interesting, because it implies possible supersymmetric particles just around the corner from the energies being explored at present. Discovery of supersymmetry is one of the foremost tasks of the machines of the next two decades. Supersymmetry, if discovered, will open up a whole variety of new particles and phenomena to be studied and analysed. This will influence profoundly the kind of physics that will be done in the 21st century. Supersymmetry may even have implications for cosmology.

Requiring a finite quantum theory of gravity and grand unification of all the four fundamental forces leads us to the speculative, but theoretically rich and conceptually challenging framework of superstrings. Supergravity theory would be only a low energy (at energies $\ll 10^{19}$ GeV) effective theory of such a superstring theory. While TeV supersymmetry will perhaps be discovered experimentally in the next decade or so, let us hope that some evidence, even if cloudy, for stringy ideas may also emerge early in the 21st century.

New ideas on acceleration to Planckian energies

Abhijit Sen

Institute for Plasma Research, Bhat, Gandhinagar 382 424, India

A plasma can sustain electric fields that are many thousands of times stronger than those of the most powerful present-day conventional particle accelerators. Plasma-based accelerators thus offer exciting new possibilities and point towards superhigh energies in the future – a promising first step towards Planckian energies.

THE primary motivation for building particle accelerators of ever-increasing energy has come from high energy physics. Starting from the thirties when cyclotron accelerators generating energies of a million electron volts (MeV) provided the necessary tools to study nuclear reactions in the laboratory, the modern day synchrotrons and linear accelerators of up to trillion electron volts (TeV) are helping us probe the fundamental forces of nature and understand the conditions of the early universe. They provide the only controlled and direct means of testing theoretical models, such as the standard model, and explore questions and problems beyond the realm of these models. Unfortunately, the conventional accelerator technology is approaching practical limits and cannot take us to the energy range of interest to high energy physics in the near and long-term future. What are these energies? In the near term, the interest lies in the 10 TeV–100 TeV range where deviations from the standard model can be tested. And in the long term if quantum gravity, the ultimate frontier of high energy physics has to be explored, then one must attain Planckian energies which are of the order of

10^{19} GeV. Conventional accelerators certainly cannot take us there. Infact, the operating principle on which the present-day accelerators are based is about half a century old and one has more or less reached the limits of technology here. Basically these accelerators use strong magnetic fields to guide particles which are propelled by strong electric fields created in vacuum by RF sources. The guide field cannot be raised substantially since they will exceed the structural forces of the magnetic materials used and the electric field strengths are likewise limited by material breakdown limits. The maximum electric field one can obtain is about 1 MV/cm, i.e. 100 MV/m. Thus, to accelerate particles to 10 TeV, one needs to construct an accelerator that is about 100 km in length. The enormous capital costs and the engineering complexities involved in building such devices considerably diminish their future viability. The cancellation of the Superconducting Supercollider (SSC) is a telling example of the kind of fate that can befall such devices. It also underscores the need to come up with new ideas and look for alternative schemes.

Fortunately, plasma particle acceleration, a new technology that has made rapid advances in the past few years, offers a promising alternative. A plasma is a state of matter which is at a temperature where all the atoms are completely ionized. Such a state has overall charge neutrality but local imbalances in charges can give rise to large longitudinal electric fields. These fields, which cause the plasma electrons to oscillate back and forth around the massive ions – the so-called plasma oscillations – can be effectively used for particle acceleration.

Unlike in a conventional accelerator, these are not dc fields – in fact a plasma strongly opposes the existence of dc fields – but one is talking here of oscillating fields due to travelling waves. Thus, to accelerate particles one has to have them moving nearly at the speed of the wave so that in the moving frame the fields appear to be almost dc. Since a plasma is already an ionized medium, it is not subject to any further electron dissociation (electrical breakdown) and hence the accelerating electric fields can, in principle, be thousands of times stronger than what conventional accelerators can provide. Typically, the maximum electric field is proportional to the amplitude of the charge imbalance (fluctuation) and to the square root of the plasma density. Plasma densities in the range of 10^{16} cm^{-3} to 10^{21} cm^{-3} are not difficult to produce in the laboratory and the maximum electric fields that they can sustain can therefore be of the order of 100 MV/cm to 30 BV/cm. These are about a factor of 10^3 superior to conventional RF systems. With such fields a plasma accelerator, of only a few 100 metres length, can produce the acceleration energies of the 87 km SSC!

How does one create these fields in the plasma to accelerate particles? I will discuss here the basic principles of two promising methods – the Beat Wave Accelerator and the Wake Field Accelerator. I will summarize their theoretical and experimental achievements to date and briefly discuss their prospects as practical accelerator devices of the future.

Plasma beat wave accelerator

The basic idea of plasma-based accelerators relies on the generation of electrostatic plasma waves travelling close to the velocity of light. Such plasma waves can then readily accelerate electrons to the required energies. In the plasma beat wave scheme, such waves are excited by mixing two collinearly propagating laser beams with frequencies ω_1 , ω_2 and wave vectors \mathbf{k}_1 , \mathbf{k}_2 such that their frequency difference matches the plasma frequency, i.e. $\omega_1 - \omega_2 = \Delta\omega \sim \omega_p$. The electrons respond resonantly to the beat frequency and give rise to large plasma oscillations. The wavenumber of the plasma wave is given by $k_p = \Delta k = \mathbf{k}_1 - \mathbf{k}_2$ and its phase velocity $v_{ph} = \omega_p / k_p$ is then equal to the group velocity of light in plasma $v_g \approx \Delta\omega / \Delta k \approx c(1 - \omega_p^2 / \omega_1^2)^{1/2}$ if $\omega_1, \omega_2 \gg \omega_p$. If a charged particle is injected into this wave at approximately the same velocity as the wave then it will stay in phase with the field, absorb energy from it and steadily accelerate. The process is analogous to a surfer gaining energy from an ocean wave as he rides the wave and slides down its slope. The idea of the beat wave scheme was first put forward by T. Tajima and J. M. Dawson¹ in a classic paper in 1979.

The strength of the longitudinal electric field E can be estimated approximately from Gauss's law, $\nabla \cdot E \approx ik_p E = n_1$ where n_1 is the oscillating density perturbation. This gives the result

$$E = |\phi k_p| \approx 0.96 \epsilon \sqrt{n_0} \text{ V/cm},$$

where ϕ is the wave potential, $\epsilon = n_1/n_0$ is the plasma wave amplitude and n_0 is the plasma density expressed in cm^{-3} . An electron falling through this potential will gain an energy ΔW given by

$$\Delta W \approx 2\epsilon \gamma_{ph}^2 mc^2,$$

where γ_{ph} is the relativistic Lorentz factor $\gamma_{ph} = (1 - v_{ph}^2/c^2)^{-1/2} \approx \omega_1/\omega_p$. Substituting for γ_{ph} we see that

$$\Delta W \approx 2\epsilon mc^2 \omega_1^2 / \omega_p^2.$$

Thus for a chosen frequency ω_1 the accelerating gradient E is maximized for large ω_p but the corresponding maximum energy gain ΔW is reduced due to the inverse dependence on ω_p . As the electron gains energy from the wave, it slips forward in phase and this dephasing limits the maximum energy gain. The length over which this dephasing occurs is given by

$$L \approx \frac{\Delta W}{eE} = 2\gamma_{ph}^3 / k_0.$$

The energy limit due to dephasing can be overcome somewhat if the electrons move at an angle to the direction of the wave propagation – again much like a surfer riding a wave at an angle to get a longer ride and move faster. The electrons can be made to move at an angle by applying a magnetic field perpendicular to the plasma wave's direction. Other factors that can limit the interaction length are diffraction of the laser beams, pump depletion of the laser beams and turbulence effects. At high laser intensities the plasma dielectric properties favour a self-focusing of the laser light, thus compensating for the diffraction effects. Likewise, the radial electric fields of the plasma waves help keep the accelerated electrons in focus. The accelerated electrons also give rise to a strong current which produces strong confining magnetic fields and aid the unimpeded progress of the electrons along the axis. Laser-induced turbulence, which impedes the formation of plasma waves, can be minimized by shortening the laser pulse length. The idea is to operate on time scales over which the ions remain virtually stationary so that ion sound waves cannot be excited. With the advent of nanosecond (and now picosecond) laser pulses, it is possible to avoid plasma turbulence over extended lengths. Many of these phenomena have been extensively investigated and tested in computer simulations.

Figure 1. Schematic of the UCLA Plasma Beat Wave Accelerator experiment (courtesy C. J. Joshi).

There have also been a large number of experiments on the beat wave scheme starting almost from the time of its first proposal in 1979. One of the leading contributors is the Indian physicist C. J. Joshi, who began his early experiments in Canada and then achieved some spectacular results in a series of experiments at UCLA². The initial experiments established the generation of large-amplitude plasma waves. Subsequently acceleration of externally injected electrons to progressively higher and higher energies has also been observed. In the UCLA setup, typically, a two-frequency beam from a 200-GW CO₂ laser (with wavelengths of 10.5 and 10.2 μm) is focused into the plasma as shown schematically in Figure 1. A 2-MeV electron beam generated in a linac is passed through this plasma region. The temporal and spatial properties of the plasma oscillations generated by the beating laser waves are studied by optical scattering techniques. The electric fields are directly probed by measuring the energy gain or loss of the electrons. A maximum energy gain of 28 MeV corresponding to an acceleration rate of 2.8 GeV m⁻¹ has been observed³. The density perturbation of the plasma wave is about 23% and the ambient density is around $9 \times 10^{15} \text{ cm}^{-3}$.

Plasma wake field accelerator

One of the major technical complexities of the Beat wave Accelerator Scheme is the resonant matching

condition, which requires that the frequency difference of the two laser beams be equal to the plasma frequency. This puts severe constraints on the required uniformity of the plasma. Nonuniformities because of ambient electron density gradients or because of random density fluctuations cannot be tolerated. An alternative scheme, called the Laser Wake Field Scheme is a more rugged and simple method in which plasma waves are created by a sudden impulse with a short and intense laser pulse. The laser pulse rise time is of the order of a plasma period. Just as a speeding boat pushes the water aside at the prow and leaves a wake behind it, the laser pulse pushes aside the plasma electrons which rush back at the exit of the pulse and give rise to plasma oscillations. This plasma wake travels at the group velocity of the laser pulse. Electrons placed in the wake field can then be accelerated in the same fashion as discussed in the previous section. Wake fields can also be generated in a plasma by using a short bunch of energetic electrons instead of a laser pulse – it is then called the electron beam wakefield accelerator. For optimum gain it is necessary to tailor the driving beam profile so that it has a slow rise (over many plasma periods) followed by a rapid falloff.

The wakefield concept has also been extensively studied in computer simulations and detailed theoretical analyses. Two of the key questions in this scheme relate to the nature of the nonlinearly coupled electromagnetic and plasma wave excitations in a cold plasma with rela-

tivistically intense laser fields and the typical group velocity of such structures in the plasma. In this context, some exact one-dimensional nonlinear solutions for modulated light pulses coupled to plasma waves have been recently analysed⁴. The solutions are in the form of soliton pulses which may be viewed as a light wave trapped in a plasma wave that it generates itself. The front of the pulse generates the plasma wave, which is then reabsorbed by the tail of the pulse. Such pulses are not only of interest for particle acceleration but can be used for photon acceleration as well. Numerical results also give a fairly accurate estimate of the group velocity of these pulses and elucidate the nonlinear relationship between the group velocity, amplitude and frequency of the wave. Some of the other limitations discussed for the beat wave accelerator e.g. diffraction effects, pump depletion, etc. also apply to the wake field accelerator. Ideas such as relativistic guiding and plasma density channels have been proposed for overcoming diffraction effects. A novel idea that has been recently proposed⁵ envisages the use of an active medium that can not only continuously replenish the loss of the laser energy to the wakefield (thereby eliminating pump depletion) but also accelerate the group velocity of the pulse to a desired value (thereby maintaining phase resonance with the trapped electrons).

Early experiments on the wake field accelerator (using electron beams as drivers) were done by David B. Cline *et al.*⁶. Direct observations of the laser wakefield accelerator have recently been reported by Roger Falcone and his colleagues⁷. Experiments at the Institute of Laser Engineering⁸ at Osaka report generating laser wakefields with gradients of 30 GV/m over a distance of 0.6 mm.

Future prospects

Plasma-based accelerators are an active area of research today and a great deal of theoretical and experimental work is in progress. Several variants of the above two basic schemes, such as the inverse free electron laser, the inverse Cerenkov accelerator, laser driven grating Linac, etc., also exist and are receiving increasing attention. The beat wave scheme is probably the one that has been the most actively pursued. Major experiments are being carried out at UCLA in the USA, the Imperial College, London and the Rutherford Appleton Laboratory, Didcot in the UK and at the Ecole Polytechnique, Palaiseau in France. In a recent collaborative experiment between these centres, gradients of 100 GV/m were observed (maximum measured energy gain of 44 MeV in 350 μm). This is by far the highest collective-wave field ever produced in the laboratory.

In view of all this recent experimental progress, the prospects of accelerating a significant number of electrons to one GeV energy in the near future appear very

Table 1.

Laser wavelengths	1.05 μm and 1.06 μm
Plasma density	10^{17} cm^{-3}
Plasma source	Multiphoton ionization
Laser pulse length	4 ps
Laser power	14 TW
Laser spot size (2σ)	200 μm
Rayleigh length (Z_0)	3.1 cm
Plasma homogeneity	$\pm 7\%$
Peak plasma wave amplitude	0.5
Peak gradient	160 MV/cm
Final energy	1 GeV

promising. The technologies associated with the laser, plasma and the electron beam injector are available and the key issues related to plasma production, plasma wave excitation, control of instabilities and optimization of the acceleration process appear to be sufficiently well understood. On the basis of this progress, there has recently been a proposal⁹ to construct a 1 GeV plasma beat wave accelerator by the UCLA group. Table 1 lists the principal parameters of this proposed accelerator. The main goal of this experimental accelerator would be to demonstrate the acceleration of a substantial number of electrons (of the order of 10^8) to about 1 GeV energy with a reasonable energy spread without the need to employ laser beam guiding.

If this experiment is funded and if the pace of present progress continues, it is not unreasonable to expect the construction of 500 GeV machines based on plasma concepts within the next decade. What about Planckian energies? The plasma accelerators that we have just discussed and which rely on electrodynamics certainly cannot get us there. The maximum laboratory-produced plasma densities we can expect are of the order of 10^{27} cm^{-3} which could yield electric fields of the order of 10^6 GV/m . So to achieve an energy gain in the Planckian regime (i.e. 10^{19} GV) we would need an accelerator of 10^{13} m length! We, therefore, need to make a few more quantum leaps and dream up some more crazy ideas. What about tapping Quark Gluon Plasma (QGP) fields? Typically, if one considers the energy density in a hadron to be of the order of 2 GeV-fermi^{-3} , then the colour fields which can be of the same order of energy density can be estimated to be about $\sim 3 \times 10^{14} \text{ GV/m}$. Of course, such fields would only accelerate confined particles (quarks) but if one argues that the colour fields would also be strongly coupled to electrodynamic fields, then one is talking of very large electric fields indeed which could be used for electron acceleration. The energy gain would be severely limited though by length constraints (extent of the QGP). One can well speculate, therefore, about an entirely new technology – a QCD-based technology¹⁰. Such a development is not unconceivable and may happen sooner than we imagine. Meanwhile, plasma accelerators have

certainly shown us a path to overcome the limitations of the present accelerator technology and move towards multi-TeV energies. This should serve as an encouragement to dream of higher goals.

High Energy Physics in the 21st century – A summary

R. Ramachandran

Institute of Mathematical Sciences, Madras 600 113, India

NOT too long ago there was a startling suggestion by Stéphen Hawking asking whether the end of Theoretical Physics was in sight. This was soon after the euphoria that accompanied the emergence of the string theory as a possible Theory of Everything and a feeling that there was now a satisfactory explanation for at least all of basic issues. After about ten years, we now perceive that unless new ideas for particle acceleration emerge, experimental high energy physics may be at an end. And that indeed can have a deleterious effect on theoretical High Energy Physics as well.

Particle Physics is, indeed, on important cross-roads at the moment. As described by D. P. Roy, we now have a standard model, with almost all experimental data in the energy range up to about TeV (10^{12} eV) accounted for, by means of about 20 parameters in a quantum field theory with adequate local symmetry. There are many hints as to what lies beyond the standard model and it is only to be expected that the situation will become clear once the experiments, currently being pursued, provide the necessary data.

As a check list, it is worth drawing up a collection of an immediate set of problems for the early 21st century as was done by Gross, Witten and Kane as a part of their assessment of outstanding questions:

(i) What determines the gauge symmetry at ordinary (?) energies (1 TeV) to be $SU(3)_c \otimes SU(2) \otimes U(1)$; $SU(3)$ signifying quantum chromodynamics and $SU(2) \times U(1)$, the unified electroweak theory of Salam and Weinberg?

(ii) How will gravity enter this picture? Through superstrings?

(iii) What is the nature of unification of the familiar forces? Is there a grand unified gauge symmetry group relevant at higher energies? Is such a unification a forerunner to incorporating gravity?

(iv) What constrains the quantum numbers of quarks and leptons? Why are the left-handed and right-handed fermions different? Is there a fundamental reason for us to have 'chiral' fermions?

(v) Why do we have different families or generations of fermions? How many? (The old version of the same question was asked by Rabi: Who ordered muon?)

(vi) What is the physics of Yukawa coupling? (What determines the masses and mixing angles of the quarks and leptons?)

(vii) Most abundant constituents of all matter are (u , d) quarks and electrons. Why are they so light in comparison with W^\pm , Z , top quark, Higgs (?) which appear to be in the 100 GeV range, presumably the natural scale of the theory.

(viii) Why is the vacuum energy (cosmological constant Λ) vanishing? How can we ensure this when the supersymmetry (boson \leftrightarrow fermion symmetry) is broken, as it indeed must.

We can be sure that as we provide answers to these issues, new queries will arise.

We observe that the main theoretical tools, that we now use, to answer the many puzzles, appear to be tak-

ing a somewhat universal shape; seem to be endowed with abilities to answer many varieties of phenomena in diverse fields. And this is a welcome trend. There has been considerable sharpening of the ideas in relativistic quantum field theory and symmetry principles. Kaul has described how supersymmetry is helpful in explaining certain notions of 'naturalness' and how different energy scales coexist in our theoretical framework. Supersymmetry, appears to have special virtues. It helps tame infinities in theories with scalar fields, which in turn are necessary for spontaneous symmetry breaking by Higgs phenomenon since fermion and boson loop divergences are negative of each other and protect the hierarchy of energy scales. Further, it provides a natural explanation for the vanishing of the cosmological constant (since there is a neat cancellation of all zero point energy in a supersymmetric quantum world). Perhaps direct evidence for supersymmetry is just around the corner.

One of the exciting developments in the closing stages of the twentieth century is the emergence of the string theory. This has turned out to be an incredibly rich framework and the string experts feel that it will have applications not only in understanding basic aspects of High Energy Physics, but will be of value in many other disciplines as well. Among its properties are many new hidden symmetries. It comes endowed with many kinds of dualities – for instance, indicating a relationship between one string theory with a coupling parameter g with another with a coupling parameter $1/g$. This opens up a possibility of understanding the strong coupling regime of one theory by looking at the weak coupling (and hence well understood) aspects of another related string theory. What is more, string theories have greater control over singularities by virtue of the presence of a natural length scale in it. Further, superstring theory, which incorporates supersymmetry as well, has ingredients of a renormalizable field theory of all interactions that encompasses all known forces of interaction and species of matter. The versatility of the theory is such that it has resulted in hitherto unknown proofs in the geometry of manifolds and this has made an impressive impact in some areas of pure mathematics.

On the experimental side, Particle Physics has always depended on large projects involving many institutions and a very large number of physicists. We seem to need gigantic accelerators (and hope to reach 200 GeV in e^+e^- collisions by the turn of the century and make a jump from 2 TeV for $p\bar{p}$ at Fermilab tevatron to 14 TeV at the CERN Large Hadron Collider in the first decade of the next century) and complex detector systems that go with them. The accelerator-based HEP is supplemented by the 'underground' labs to do precision measurements making use of solar and atmospheric neutrinos and other exotics and further look for signals from astroparticle physics-related observations. In the 21st century, the need will be to push to higher energies as well as to

higher precision. Both require innovative efforts as pointed out by Cowsik and Sen.

There is much concern that the projects in High Energy Physics are getting bigger and more expensive. SSC (Superconducting Super Collider) at Texas had to be abandoned as unaffordable. There is a perception of growing fatigue in the support of science for science-sake. It is suggested that there are more deserving claimants for the public support and there is a perennial debate between 'big' science and other sciences. It is unfortunately forgotten that the quest for new acceleration techniques and new principles of particle detection, identification and computing, etc, will have a direct impact not only in High Energy Physics, but in a whole variety of disciplines. It is inescapable that there will be direct consequences for: Condensed Matter Physics, basic as well as applied areas; advances in information technologies/computing/data handling (WWW – the world wide web of distributed information network had originated from CERN); and many aspects of Material Science. Indeed, Experimental Particle Physics may be the most efficient way to develop high-tech applied sciences.

It is with this background that we should review the programme of Experimental High Energy Physics in India. In the past, our efforts had banked on (i) cosmic ray experiments (ii) analysis of emulsion stacks and bubble chamber data from High Energy Physics experiments elsewhere (iii) KGF underground laboratory for proton decay and ν interactions and (iv) experiments at CERN and Fermilab. At present, we play important roles in both CERN LEP experiments (L3 collaboration) and Fermilab efforts (DØ collaboration). In the future there are plans for active participation in the Large Hadron Collider project at CERN ($p\bar{p}$ collider at centre of mass energy of about 14 TeV in the LEP tunnel) both at the stage of construction of the accelerator and later on in doing physics experiments with it.

We should, I believe, think in terms of supplementing these efforts by activities based in India. It will be useful to initiate thinking about various options we may pursue. For instance, let me start with a short list for active consideration:

- (i) A new innovative 'underground' laboratory, with international funding and participation.
- (ii) A new task force (think tank?) as suggested by Rajasekaran for new principles of particle acceleration (Planckian?).
- (iii) A time-bound programme for building a high energy accelerator in India, say in the range 10 GeV–20 GeV, targeting a specific niche. The aim should be for a unique device, say, for example, to study high precision polarization (beam/target) phenomena. We may thus look forward to having a component of High Energy Physics activity based in India in the not-too-

distant future, so that our national efforts complement our commitment to the collaborations elsewhere.

To conclude, what, may we expect, the shape of 21st century High Energy Physics to be? It is worth recalling that in the early sixties, particle physicists *expected* (i) to reach the region of asymptotic flat cross-sections, signifying the diffraction scattering of strongly interacting particles as being due to dominant Pomeron exchange at 60 GeV (at that time, next high energy (ISR: intersecting storage ring) machine), and the culmination of Regge Theory; and (ii) made bold predictions that the intermediate vector bosons that mediate weak interaction

could be as heavy as 2 GeV! However we now find that (i) W^\pm , Z have masses 40 to 46 times heavier! and (ii) there is no hint of asymptopia, but we have something much better. A gauge theory of strong interaction described by QCD!! Regarding the future, therefore, it would be hazardous to make any guess; maybe the space-time will be granular and new paradigms will begin to take shape. Perhaps any guess that we now make may not be wild enough.

I would like to, nevertheless, believe that 'particle physicists are grappling with wonderful questions and marvelous and mysterious ideas'. No marks for guessing who said this.

**RAJIV GANDHI INSTITUTE
FOR CONTEMPORARY STUDIES
(Rajiv Gandhi Foundation)**

in collaboration with

**JAWAHARLAL NEHRU CENTRE FOR
ADVANCED SCIENTIFIC RESEARCH**

offers

**RAJIV GANDHI RESEARCH GRANTS
FOR INNOVATIVE IDEAS IN SCIENCE & TECHNOLOGY
for the year 1996–97**

Advt. No. 12/96

July 8, 1996

These grants (Rs. 2 to 3 lakhs) are available to a select number of young Ph Ds (below 45 years of age) working independently in Universities, National Laboratories and other organizations, who badly require seed money to try out innovative ideas in science and technology. Persons interested may send project proposals along with their bio-data through the heads of their organization before the end of **August 1996** to:

A new technique for visualization of shock shapes in hypersonic shock tunnel

G. Jagadeesh, B. R. Srinivasa Rao,
K. Nagashetty, N. M. Reddy and K. P. J. Reddy

Department of Aerospace Engineering, Indian Institute of Science,
Bangalore 560 012, India

Based on the principle of dependence of the intensity and the spectrum of the spontaneous light emitted in an electrical discharge on the density and the temperature of the gas along the discharge path, a technique for flow visualization around the bodies flying at hypersonic Mach number is developed. The shock shapes over a flat plate with sharp leading edge at different angles of attack are visualized using this technique in IISc hypersonic shock tunnel HST1 at flow Mach number of 5.75. The visualized shock wave angles match very well with the theoretical values. The details of this new technique along with a few sample results are presented here.

THE flowfields around hypersonic vehicles are very complex and measurement of these flowfields is important for their understanding. The flow visualization is

conventionally achieved by employing optical systems, such as the schlieren method, interferometry, shadowgraphs and holography. Except holography, none of the other systems is useful for three-dimensional shock wave visualization because the visualization in these systems is achieved by passing the light along the optical axes perpendicular to the direction of the gradient of the gas density. On the other hand, the holographic technique is very sensitive to mechanical vibrations and hence is very difficult to use for the flow visualization in the wind tunnel tests.

A simpler technique based on the electrical discharge for the visualization of three-dimensional shock shapes around hypersonic vehicles has been reported recently¹. This technique is based on the principle that the intensity of spontaneous radiation emitted by the ion recombination in an electrical discharge depends on the gas density along the discharge path². In this method when an electrical discharge is generated across a shock wave, the light emitted from the shock wave region will be very weak compared to that from the freestream and the shock layer. As a result, the shock shape appears as a dark line in the intensity field. However, the electrical discharge technique has been developed for the flow visualization in a hypersonic wind tunnel where the test time is above 10 milliseconds. In this paper we report a

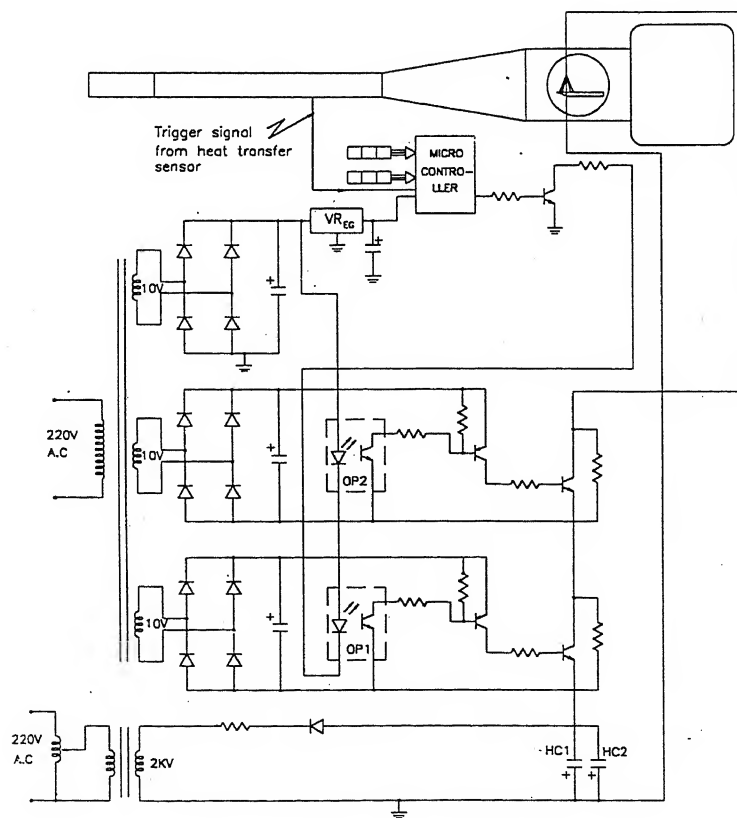

Figure 1. Schematic diagram of a hypersonic shock tunnel with the circuit diagram for the generation of electrical discharge of 2 μ s duration across the pair of electrodes inside the test section.

Figure 2. Arrangement of point and line electrodes for the visualization of shock shapes around the flat plate model.

new electrical discharge technique for the visualization of flow in hypersonic shock tunnel where the test time is less than a millisecond. The shock shapes around a flat plate with a sharp leading edge at flow Mach number 5.75 are visualized using this technique in IISc hypersonic shock tunnel HST1. The measured shock angles match very well with the predicted values at various angles of attack.

A schematic diagram of the IISc hypersonic shock tunnel HST1 along with the electrical circuit for the generation of the electrical discharge across the test model is shown in Figure 1. Freestream Mach numbers up to 13 can be generated in this tunnel using a nozzle with appropriate area ratio. A conical nozzle with an exit diameter of 30 cm expands the flow into a 45 cm long test section of 30 cm \times 30 cm area. Two optically clean windows are provided for photographing the discharge phenomenon in the test section.

The electrical discharge is generated across a point electrode and a line electrode. The point electrode of 1 mm dia is suspended in the freestream inside the test section while the line electrode made out of a 0.5 mm thick copper strip is embedded in the test model such that one of its edges is flush with the top surface of the model. The electrodes are kept about 60 mm apart. The test model is made out of bakelite material to ensure insulation of the rest of the tunnel from high voltages and also to avoid multiple reflections from the model surface. The details of the flat plate and the electrode arrangement are shown in Figure 2.

The details of the electrical discharge circuit developed for the purpose of generating discharge between

the electrodes are shown in Figure 1. Since it is critical to ensure the occurrence of the discharge after the flow attains steady state in the test section, a circuit is built for delaying the occurrence of the discharge after receiving the trigger signal with a facility to limit the discharge duration. The trigger signal for the circuit is obtained from a platinum thin film sensor located towards the end of the shock tube mounted flush with the inner surface of the driven section. The sensor generates an electrical pulse corresponding to the rise in temperature due to the arrival of the shock wave. This pulse becomes an input signal to the microcontroller encompassing an 8 bit 8031 microprocessor, a 2764 EPROM and a couple of digital switches. This controller has facility for adjusting a delay and the pulse duration. The delay is carefully adjusted such that the electrical discharge is generated after the nozzle starting process is complete and a steady flow is established in the test section. The delayed signal acts on two optical couplers OP₁ and OP₂, which have an integrated LED and a phototransistor. When activated, the light from the LEDs is sensed by the phototransistors and the photocurrent generated from these diodes will switch on the high voltage transistors BU 205s connected in parallel. This closes the electrical circuit and the high voltage is applied between the pair of electrodes by electrical charge stored in the condensers HC₁ and HC₂ which generates the discharge. After the time lapse set by the pulse duration the microcontroller sends an interrupt signal which will turn off the high power transistors and break the continuity of the electrical circuit terminating the electrical discharge.

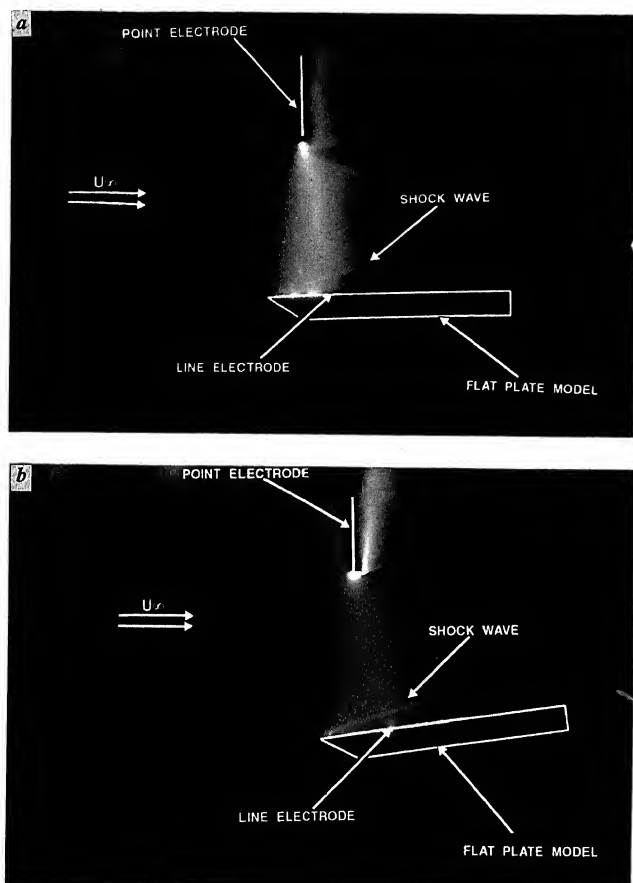

Figure 3a, b. The shock waves over a flat plate with a sharp leading edge inclined at (a) 5° and (b) 6° to the flow direction inside the test section of the HST1 tunnel at Mach number 5.75.

The experiments were conducted with the following test conditions: flow Mach number = 5.75, Reynolds number = $1 \times 10^5 \text{ m}^{-1}$, freestream density = $1 \times 10^{-2} \text{ kg/m}^3$, duration of the steady flow ~800 μs , freestream temperature = 173 K and freestream static pressure = $9.9 \times 10^{-3} \text{ mbar}$. In these experiments the point electrode was used as the anode and the line electrode was used as cathode. The voltage applied across the electrodes was about 1500 V and the electric current was set at 1 A. The discharge in the test section was photographed from outside the side window using a Nikon FM 2.8 camera with B exposure. A film with ASA 1600 speed was used for recording the weak light emitted from the discharge field. Some of the photographs were taken at film speeds of ASA 3200 and ASA 6400 by using the push processing technique in order to record the spectral variation of the light emitted from the temperature layer. However these preliminary experiments did not reveal the temperature layer because the temperature in this layer will be very low for the flat plate with a sharp lead-

ing edge. Currently the efforts are being made to study the temperature layer with a blunt nose cone model.

Typical results of the shock shape visualization are shown in Figure 3a and b for the flat plate at 5 and 6 degrees angle of attack, respectively. Unlike the dark line representing the position of the shock wave in the long-duration tunnels¹, the shock position in these figures is indicated by the bright line. The bright portion at the shock wave occurs in this case because the experimental conditions are suitable to make the electron energy at the shock wave equal to about 20 eV (ref. 3). The measured shock wave angles of 13° and 14° match very well with those theoretically estimated using oblique shock relationship⁴ for both the cases.

In conclusion, we have demonstrated a new technique for the visualization of the shock shapes around the hypersonic vehicles tested in hypersonic shock tunnel. This method is novel as it suits application in the shock tunnel where the typical test times are less than a millisecond. The measured shock angles for a flat plate with sharp leading edge at an angle of attack tested at flow Mach number 5.75 in IISc shock tunnel HST1 match very well with the theoretical results. This technique can be utilized for visualizing the three-dimensional shock shapes by taking the photograph of the electrical discharge either in the downstream or upstream direction of the flow.

Steric enhancement of resonance: An electron localization perspective

Shridhar R. Gadre, Libero J. Bartolotti* and C. H. Suresh

Department of Chemistry, University of Pune, Pune 411 007, India
*North Carolina Supercomputing Center, 3021 Cornwallis Road, Research Triangle Park, NC 27709, USA

Steric enhancement of resonance (SER) has earlier been characterized in terms of molecular properties such as dipole moment, bathochromic shift, mesomeric moment, spin–spin coupling constant or by monitoring the kinetics of a reaction. The present work provides a unified picture of SER in terms of the electron localization patterns in a molecule.

THE phenomenon of steric hindrance of resonance (SHR) has been well documented¹ in the organic chem-

istry literature for a long time. However, that of steric enhancement of resonance (SER) has been discussed²⁻⁸ rather scantily and only for the past three decades or so. SER was first noticed by Baliah and Uma² during their dipole moment measurements of some substituted anisoles. Later, Kamlet *et al.*^{3,4} invoked the same phenomenon for explaining bathochromic shifts observed in the absorption spectra of some alkyl nitrobenzenes and substituted 2,4-dinitroanilines. Similarly, the higher rates of solvolysis (4 times) shown by 3-methyl 4-methoxy benzylchloride, as compared to 4-methoxy benzylchloride have been explained in terms of the SER phenomenon⁵. Some other physical data in the literature supporting this phenomenon are: the calculated and observed dipole moment values for 2,4-dinitroanisole and 1-methoxy-2,4-dinitronaphthalene⁶, the spin-spin coupling constants between the methyl protons and the ortho ring protons of a number of substituted anisoles⁷ and the ¹⁶O and ¹³C NMR chemical shifts of 2-substituted, 2,6-disubstituted and 2,4,6-trinitroanisoles⁸. In the above-mentioned works, SER manifests in many diverse ways. The question addressed in the present communication is: can one obtain a common electronic signature for these wide-ranging physico-chemical observances regarding SER?

The recent works done by Gadre *et al.*⁹⁻¹³ have demonstrated that MESP topography is a convenient tool for monitoring the subtle changes in electronic distribution in molecules. The MESP, $V(\mathbf{r})$, at a point \mathbf{r} due to a molecular system with nuclear charges $\{Z_A\}$ located at $\{\mathbf{R}_A\}$ and electron density $\rho(\mathbf{r})$ is given by

$$V(\mathbf{r}) = \sum_A^N Z_A / |\mathbf{r} - \mathbf{R}_A| - \int \rho(\mathbf{r}') d^3\mathbf{r}' / |\mathbf{r} - \mathbf{r}'|,$$

where N is the total number of nuclei in the molecule. The terms on the rhs of the above equation represent the nuclear contribution and the electronic contributions respectively. When the electronic factor overrides the nuclear one, $V(\mathbf{r})$ becomes negative and a large negative value for it physically implies a higher electron localization around that point. These points of maximum electron localizations or minimum MESP value can be rigorously characterized by the topological analysis⁹⁻¹³ of MESP based on the identification and location of its minima.

In general SER phenomenon can occur in two ways^{4,5}. In the first case, it may occur in a system such as **1** where, X is a $+R$ or $+I$ substituent and Y and Z are $-R$ substituents⁴. It follows that progressively increasing the bulk of X forces Y from out of the ring plane, and this leads to a decrease in the power of Y to withdraw electrons from the ring and X . This is the classical situation of SHR. A counter-effect of this leads to the enhancement of the resonance interaction between X and Z and is termed as SER⁴. The second situation is observed in

Figure 1.

substituted anisoles or thioanisoles^{2,5}. When a substituent is present ortho to the methoxyl group, the free rotation of the $-OCH_3$ group is restricted and it takes a preferred orientation that is anti to the 2-substituent and coplanar to the ring plane. This geometry enables the methoxyl group to conjugate more effectively with the group at the 4-position.

We have explored **2**, **3** and **4** (Figure 1) as test examples towards an appraisal of SER in terms of features of electron distribution. Our earlier MESP topographical analysis of substituted benzenes¹² demonstrated that the orientation effect as well as the activation or deactivation exhibited by the substituents can be very well represented by the position and the values of the MESP minimum. It was also found that using a molecular geometry optimized at a lower basis-set (typically 6-31 G) and a wave function obtained at a higher basis-set (usually 6-31 G**) is generally quite sufficient for an adequate topological representation of MESP. All the molecules reported in this work are fully optimized at HF/6-31G level using GAUSSIAN94 (ref. 14) package. Using these geometries, the wave function at HF/6-31 G** level is calculated and employed for the MESP topographical analysis. Packages UNIPROP (ref. 15) and UNIVIS (ref. 16) developed in our laboratory are employed for this purpose.

In all the substituted benzylchlorides **2a-e**, the plane which contains the chlorine, the benzyl carbon and a ring carbon is perpendicular to the ring plane. When both the ortho-positions of $-OCH_3$ are occupied by $-CH_3$ group **2e** and **3c**, the plane defined by the methoxyl carbon, oxygen and a ring carbon makes an angle 90° , which otherwise makes an angle of 0° with respect to the benzene ring. The methoxyl group and the chlorine atom are seen on the same side of the ring in

Figure 2 A–C. MESP iso-surface corresponding to $-115.41 \text{ kJ mol}^{-1}$ for systems **2c**, **2d** and **2e** respectively; D–F, MESP iso-surface corresponding to $-31.48 \text{ kJ mol}^{-1}$ (blue surfaces) and $-194.10 \text{ kJ mol}^{-1}$ (red surfaces) for systems **4a**, **4b** and **4c** respectively.

3,5-dimethyl 4-methoxybenzylchloride, **2a**. In 2-nitroanilines **4a–c**, except the case of **4c** all the heavy atoms

are lying in the benzene ring plane. In **4c**, the nitro group is not in the ring plane, but exactly perpendicular to it.

Table 1. MESP minima for systems 2, 3 and 4. All values are in kJ mol⁻¹

Structure	Oxygen minimum	Chlorine minimum	Para carbon (with respect to -OCH ₃ or -NR ₂) minimum	Nitrogen minimum
2c	-176.79	-124.07	-	-
2d	-171.28	-132.72	-	-
2e	-199.87	-125.38	-	-
3a	-200.13	-	-89.97	-
3b	-195.98	-	-96.00	-
3c	-212.46	-	-87.61	-
4a	-228.46	-	-36.20	-57.44
4b	-230.82	-	-39.61	-44.59
4c	-206.69	-	-52.46	-41.97

In benzene, the MESP minimum for the π -cloud is -85.5095 (all values quoted here are in kJmol⁻¹). The substitution of one hydrogen by the -CH₂Cl group, **2a**, deactivates the ring and the MESP value of the ring minimum is increased to -51.41. The chlorine MESP minimum is -121.71 in **2a**, which in the case of methyl chloride is -94.43, indicating that the electron density around the chlorine atom is enhanced at the expense of the ring π -electron density. The electron flow towards the chlorine is further increased when one electron donating group is introduced in the aromatic ring. A methyl group at the meta position **2b** or a methoxyl group at the para position **2c** changes the minimum ESP of chlorine to -124.07 and -129.31 respectively. When both are present, **2d**, the MESP minimum of chlorine goes down to -132.72, i.e. a decrease by 11.02 units, which is a little higher than the added effect of the -CH₃ and -OCH₃ groups. By adding one more methyl group at the remaining ortho position of -OCH₃ group, **2e**, the value of the chlorine minimum goes deeper by 3.67 than the chlorine minimum of **2a**. Exactly complementary trend in the values of the oxygen MESP minimum is observed in **2c**, **2d** and **2e** (see Table 1). Oxygen minimum is less negative in **2d** compared to **2c** and it is more negative in **2e**. A decrease in the magnitude of oxygen MESP minimum is compensated by an increase in the magnitude chlorine minimum (Table 1). This feature is graphically brought out by Figure 2, wherein iso-surface of MESP with value of -115.4116 is depicted for **2c**, **2d**, and **2e** in Figure 2A, B and C respectively. The lobe of iso-surface with value -115.41 is the largest in Figure 2C for **2e** at the expense of the chlorine lone-pair. The lobe is the largest in Figure 2B for **2d**.

The changes seen in the chlorine minimum can be correlated to the kinetic data on the solvolysis of systems **2a-e** reported by Baliah and Kanagasabapathy⁵. They have explained the unusually higher rate of reaction of system **2d** and the unusually lower reactivity of **2e** by invoking the concept of SER. In their opinion, a sub-

stituent ortho to methoxyl group does not sterically inhibit the methoxyl group from conjugating with the benzene ring, but makes the conjugation more effective than in the absence of the ortho substituent. In the present context, the observation of a highly negative valued chlorine minimum in **2d** supports their argument and it points out that such a minimum may make the leaving process of Cl⁻ easier and accounts for the higher rate of solvolysis of **2d**. When both ortho positions are occupied, **2e**, the methoxyl group prefers a perpendicular orientation with respect to the benzene ring and this makes the conjugation of the oxygen lone pairs with the benzene ring difficult, hence the -I effect of oxygen decides the electron distribution.

In the absence of the electron withdrawing group -CH₂Cl, viz. in systems **3a**, **3b** and **3c**, a MESP minimum appears above the para carbon atom with respect to the methoxyl group. A comparison of the values of the para minimum and the oxygen minimum (Table 1) once again confirms the SER phenomenon.

In 2-nitroanilines **4a-c** the interplay of the steric and the electronic effects can be monitored using three different MESP minima. Here we report one of the -NO₂ oxygen minimum, one minimum seen above the para carbon and the -NR₂ nitrogen minimum (Table 1). Going from **4a** to **4b**, the oxygen minimum as well as the carbon minimum becomes more negative (the change is 2.36 and 3.41 respectively) due to the more electron push from the -NH(CH₃) group compared to the -NH₂ group. At the same time the nitrogen minimum goes up by 12.85. When the substituent is -N(CH₃)₂ the -NO₂ group goes completely out of the ring plane and this leads to a significant increase in the oxygen MESP minimum (an increase by 21.77 with respect to **4a**), visually seen in Figure 2. This explains the classical situation of SHR. A deepening of the para carbon minimum by 16.26 shows the counter effect of this phenomenon, the SER. This effect can be visually seen in Figure 2D, E and F in terms of MESP iso-surfaces with values of -31.48 and -194.10. This enhancement is due to the more electron donation from the donor as well as the diminished electron-pulling effect of the acceptor.

The above observations on the substituted benzylchlorides and substituted anisoles lead us to the following important conclusions. There is indeed a unique electronic signature of the steric enhancement of resonance phenomenon. The phenomenon can be monitored by the electron concentration patterns through the MESP topography.

Quantum chaos in Rydberg atoms: A quantum potential approach

P. K. Chattaraj and S. Sengupta

Department of Chemistry, Indian Institute of Technology, Kharagpur 721 302, India

The quantum signature of chaos in Rydberg atoms has been studied using a quantum theory of motion and quantum fluid dynamics. A hydrogen atom in the electronic ground state ($n = 1$) and in an excited electronic state ($n = 20$) behaves differently when placed in an external oscillating electric field. Temporal evolutions of Shannon entropy, density correlation, phase space distance function of Bohmian trajectories and associated Kolmogorov–Sinai entropy for these two cases show marked differences.

CLASSICAL interpretation of quantum mechanics is as old as the quantum mechanics itself. In the Madelung representation¹ the time-dependent Schrödinger equation for a single particle of mass m moving under potential $V(r)$, viz.

$$[-(\hbar^2/2m)\nabla^2 + V(r)]\Psi(r, t) = i\hbar\partial\Psi/\partial t \quad (1)$$

is transformed into two-fluid dynamical equations. Substituting the following polar form of the wave function

$$\Psi(r, t) = R(r, t) \exp(iS(r, t)/\hbar) \quad (2)$$

in eq. (1) and separating the real and the imaginary parts, one obtains an equation of continuity

$$\partial\rho/\partial t + \nabla \cdot j = 0, \quad (3a)$$

and an Euler-type equation of motion

$$\partial v/\partial t + (v \cdot \nabla)v = -(1/m)\nabla(V + V_{qu}). \quad (3b)$$

In eqs (3) the charge density, $\rho(r, t)$ and current density, $j(r, t)$ are

$$\rho(r, t) = [R(r, t)]^2 \quad (4a)$$

and

$$j(r, t) = \rho(r, t)v(r, t). \quad (4b)$$

where the velocity $v(r, t)$ can be defined in terms of the phase of the wave function as

$$v(r, t) = (1/m)\nabla S(r, t). \quad (4c)$$

The quantity V_{qu} appearing in eq. (3b) is called the quantum potential or Bohm potential of hidden variable theory² and defined as

$$V_{qu} = -(\hbar^2/2m)\nabla^2 R/R. \quad (5)$$

Therefore, in this quantum fluid dynamics¹ the overall motion of the system under consideration can be thought of as the motion of a 'probability fluid' having density $\rho(r, t)$ and velocity $v(r, t)$ under the influence of the external classical potential augmented by a quantum potential, V_{qu} .

For the ground state of a many-particle system, $\rho(r, t)$ contains all information³. In a time-dependent situation

This paper is based on a seminar talk delivered by P. K. Chattaraj in the International Discussion Meeting on Time Dependent Quantum Mechanics of Many Electron Systems at Indian Institute of Science, Bangalore in January, 1996.

also the time-dependent density functional theory^{4,5} asserts that any physical observable can be expressed as a functional of $\rho(r, t)$ and $j(r, t)$ and thus allows us to formulate the dynamics in terms of 'classical-like' 3D quantities. Although Madelung transformation in terms of $\rho(r, t)$ and $j(r, t)$ is not straightforward in a many-particle situation, we can make use of the time-dependent density functional theory in constructing two fluid-dynamical equations in 3D-space. This formalism is termed as quantum fluid density functional theory⁶ which has been applied in understanding ion-atom collisions⁶⁻⁸, atom-field interactions^{9,10} and electronegativity^{11,12}, hardness¹²⁻¹⁴ and entropy dynamics¹⁴ in a chemical reaction.

Quantum potential plays a crucial role in the quantum theory of motion¹⁵ as well. In this representation of quantum mechanics developed by de Broglie¹⁶ and Bohm¹⁷, the overall motion of the system is understood in terms of the motion of a particle experiencing forces originating from the classical and quantum potentials. The Newton's equation of motion for this particle guided by a wave (represented by $\Psi(r, t)$, a solution to eq. (1)) can be written as

$$(\partial/\partial t + \dot{r} \cdot \nabla)(m\dot{r}) = -\nabla(V + V_{qu})|_{r=r(t)} \quad (6)$$

At a particular instant the solution to the time dependent Schrödinger equation (1) fixes the velocity of the particle (cf. eq. 4c) and, hence, for a given initial position the particle motion can be studied through the solution $r(t)$ to the equation

$$v(r, t) = \dot{r} = (1/m)\nabla S(r, t)|_{r=r(t)} \quad (4c)$$

Theories based on quantum potential idea have been applied in solving various physico-chemical problems^{15,18-32}. Because of the presence of nonlinearity and also the 'classical language', these theories have been found^{15,21,22,30,32-34} to be helpful in understanding the quantum domain behaviour of a classically chaotic system which is described as quantum chaology by Berry³⁵. The quantum theory of motion, however, allows one to study the quantum chaos in a system without any resort to its classical domain dynamics¹⁵.

We adopt here a quantum potential approach to study the chaotic dynamics of a typical quantum system, viz. a Rydberg atom in an oscillating electric field. Of late, these systems have been considered to be 'veritable gold mines for exploring the quantum aspects of chaos'³⁶. It has also been discussed³⁷ that depending on the frequency and field intensity, hydrogen atom exhibits order to chaos transition when placed in an external oscillating field. Since hydrogen atom is one of the simplest possible solvable quantum mechanical systems and its classical mechanical counterpart, a Keplerian system, is known to exhibit chaotic dynamics³⁸ in presence of external field, we try to investigate the possible quantum signature of chaos in an electronically excited hydrogen

atom in presence of an external field. Both theoretical³⁹ and experimental⁴⁰ studies have been carried out on this system to understand the chaotic behaviour associated with quadratic Zeeman effect. For a beautiful review on this subject see ref. 36. In the present work we study the time evolution of Ψ_{1s} and Ψ_{20s} wave functions of hydrogen atom placed in an external oscillating electric field with $\omega = 5\pi$ and for both $F = 0$ and $F = 5$. We apply the quantum theory of motion in gaining insights into the possible chaotic dynamics in electronically excited hydrogen atom subjected to an external electric field^{36,37}.

The time-dependent Schrödinger equation (in a.u.) for the present problem in cylindrical polar coordinate system $(\bar{\rho}, z, \phi)$ is

$$[-\nabla^2/2 + V]\Psi = i\partial\Psi/\partial t \quad (7a)$$

where the potential V is given by

$$V = -1/r + Fz\cos\omega t. \quad (7b)$$

Making use of the following transformations

$$y = \bar{\rho}\Psi. \quad (8a)$$

$$\bar{\rho} = x^2 \quad (8b)$$

and integrating over $0 \leq \phi \leq 2\pi$, eqs (7) turn out to be

$$\begin{aligned} & [3/4x^3\partial y/\partial x - 1/4x^2\partial^2 y/\partial x^2 - \partial^2 y/\partial z^2] \\ & - [1/x^4 - 2V]y = 2i\partial y/\partial t. \end{aligned} \quad (9)$$

The above equation is solved as an initial boundary value problem using an alternating direction implicit method⁴¹. The resulting tridiagonal matrix equation is solved using Thomas algorithm. The mesh sizes adopted here are $\Delta x = \Delta z = 0.4$ a.u. and $\Delta t = 0.01$ a.u., ensuring stability of the forward-time-central-space type numerical scheme used here. Note that each alternating direction implicit cycle corresponds to $2\Delta t$ and atomic units of length and time are 0.5292×10^{-10} m and 2.4189×10^{-17} sec respectively.

The initial and boundary conditions associated with this problem are:

$$\text{at } t = 0, y(x, z) \text{ is known for } \forall x, z, \quad (10a)$$

$$y(0, z) = 0 = y(\infty, z) \quad \forall z, t, \quad (10b)$$

$$y(x, \mp \infty) = 0 \quad \forall x, t. \quad (10c)$$

The numerical scheme is stable⁴² due to the presence of $i = \sqrt{-1}$. As a further check of numerical accuracy we have verified the conservation of norm and energy (in zero field cases). The wave function is moved forward up to the end of simulation ($N\Delta t = 7$ a.u.) and then taken back to its initial position where the original profile is reproduced well within the tolerance limit of the present calculation. We could not, however, perform the long time simulation because of our inadequate computational facilities.

The dynamical quantities calculated in the present work are as follows:

- a) Shannon entropy given by

$$S = -k \int \rho \ln(\rho) dr,$$

where k is the Boltzmann constant.

- b) Density correlation function defined as

$$C = \int \rho^{1/2}(r, 0) \rho^{1/2}(r, t) dr.$$

We have also solved eq. (4c) using a second order Runge-Kutta method to generate the 'quantum trajectory' of a particle for a given initial position. Now, we are in a position to analyse the sensitive dependence on initial condition, a characteristic of a chaotic system. We can change the initial condition in two ways: i) by shifting the wave function slightly and ii) shifting the initial position of the particle slightly. In the first case the time-dependent Schrödinger equation is solved with both $\Psi(r, t=0)$ and $\Psi(r + \Delta, t=0)$ as inputs, $\Delta = 0.01$ while the second case deals with the solution of eq. (4c) with two different initial positions of the particle, (\tilde{p}, z) and $(\tilde{p} + d\tilde{p}, z + dz)$, $d\tilde{p} = 0$ $dz = 0.01$. Initial momentum of the particle is taken as zero in all cases. We study the time evolution of phase space distance (D) for the corresponding quantum trajectories defined as^{21,31,32}

$$D(t) = ((x_1(t) - x_2(t))^2 + (p_{x_1}(t) - p_{x_2}(t))^2 + (y_1(t) - y_2(t))^2 + (p_{y_1}(t) - p_{y_2}(t))^2)^{1/2}, \quad (11a)$$

where (x, p_x, y, p_y) refers to a point in phase space.

We also calculate the associated Kolmogorov-Sinai entropy as defined^{31,32} below

$$H = \sum_{\Lambda_+ > 0} \Lambda_+, \quad (11b)$$

where the Lyapunov exponent is given by^{31,32}

$$\Lambda = \lim_{t \rightarrow \infty} \frac{1}{t} \ln(D(t)/D(0)). \quad (11c)$$

'Quantum dynamics is chaotic if in a given region of phase space the flow of trajectories, according to the Hamilton-Jacobi formulation of quantum mechanics, has positive KS entropy'.³¹ The efficacy of this definition has already been tested in the cases of a quantum Henon-Heiles oscillator²¹, the quantum standard map³¹ and Weigert's quantum cat map³². For the sake of brevity unless otherwise specified, we present the time evolution of all quantities calculated for the non-zero field relative to the corresponding zero field counterpart. The Kolmogorov-Sinai entropy is calculated using this relative distance. In all plots the temporal variation is expressed in terms of the corresponding numerical integration step number, N .

Figure 1a, b. Time evolution of S/k , where S is the Shannon entropy and k is the Boltzmann constant, for Rydberg atom in external field: (a) $n = 1$ (b) $n = 20$.

Shannon entropy and density correlation function have been shown in Figures 1a, b and 2a, b respectively. In both the figures a and b refer to the ground state and $n = 20$ state of the hydrogen atom respectively. As is clear in these figures, the applied field causes drastic change in the dynamics of Ψ_{20s} state of H-atom whereas it hardly has any effect for the ground state. In Figures 1a and 2a we see that entropy and density correlation values for $n = 1$ state do not change when the external field is applied whereas those quantities for $n = 20$ state exhibit (Figures 1b and 2b) significant changes on application of the field of same strength as in the previous case ($n = 1$).

Figures 3a, b depict the time evolution of D and H respectively for the shifted wavepacket case. For clarity we also present the behaviour of D for the non-zero field case (Figure 3c). The distance remains the same (in fact

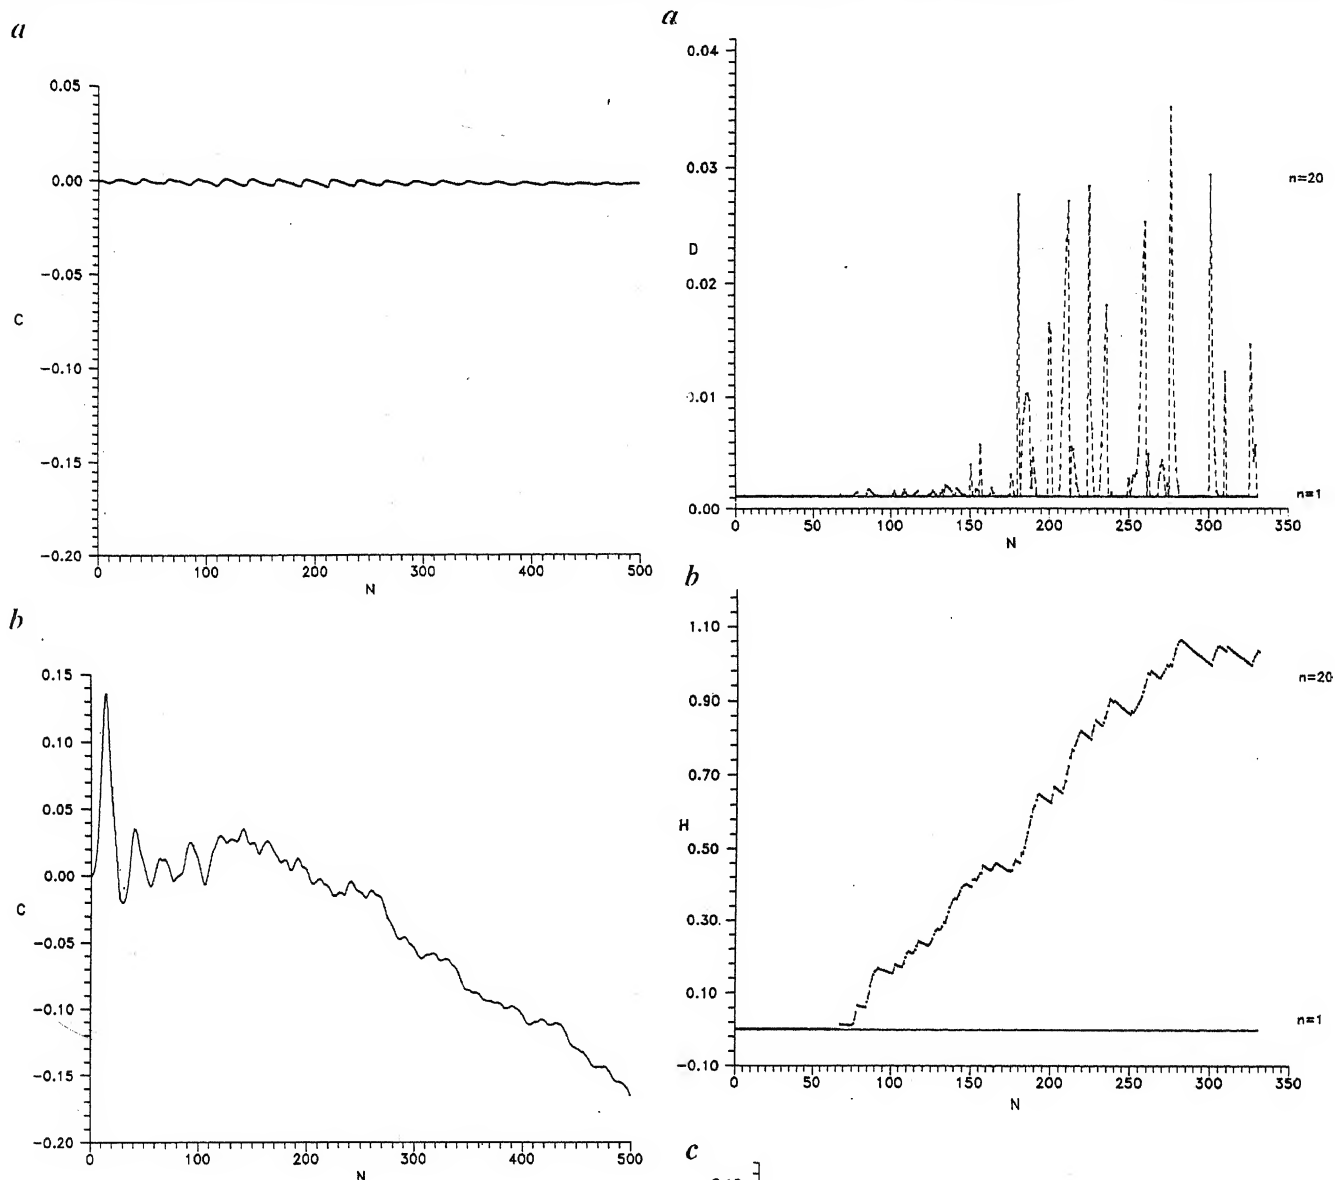

Figure 2a, b. Time evolution of density correlation function C for Rydberg atom in external field: (a) $n=1$, (b) $n=20$.

decreases at times) for $n=1$ but oscillates for $n=20$, becoming very large sometimes. Although we could simulate only up to $N\Delta t = 7$ a.u., it is clear from Figure 3b that H remains practically constant at zero value for $n=1$ while it increases rapidly to a positive value for the $n=20$ case, reflecting discernible chaotic dynamics through sensitive dependence on initial conditions. Two initially ($t=0$) nearby 'Bohmian trajectories' remain close in course of time for the $n=1$ case while they diverge for the $n=20$ case. In these figures, it is discernible that there is a time scale after which the 'chaotic' behaviour sets in. However, it needs a thorough study whether this time is related to the break-time of Chirikov and Casati³⁷. The authors are grateful to the referee for pointing this out. Corresponding D and H

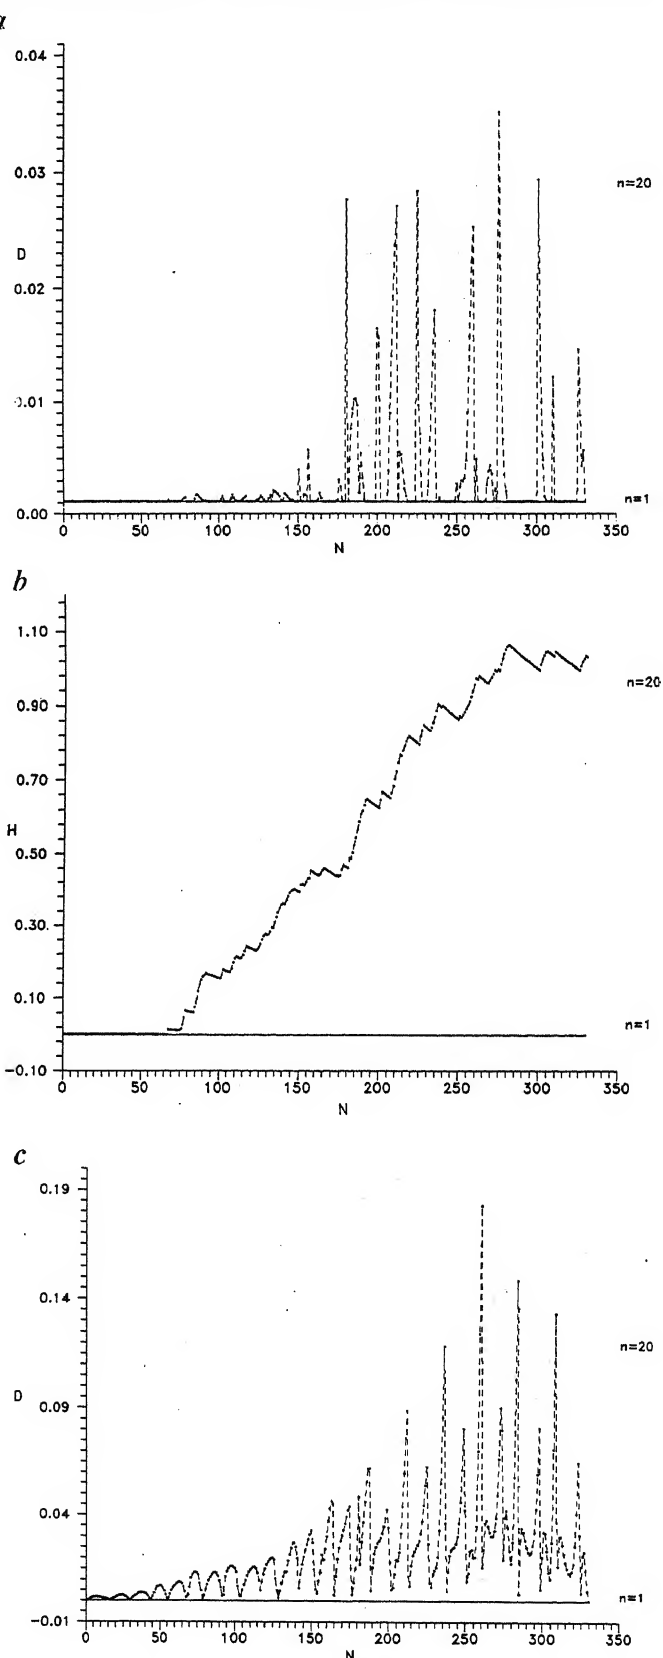

Figure 3a-c. Time evolution of phase space distance function D and KS entropy H in shifted wave function case (see text for details) for Rydberg atoms in external field: (a) D for nonzero field relative to zero field, (b) H associated with D in Figure 3a, (c) D in nonzero field.

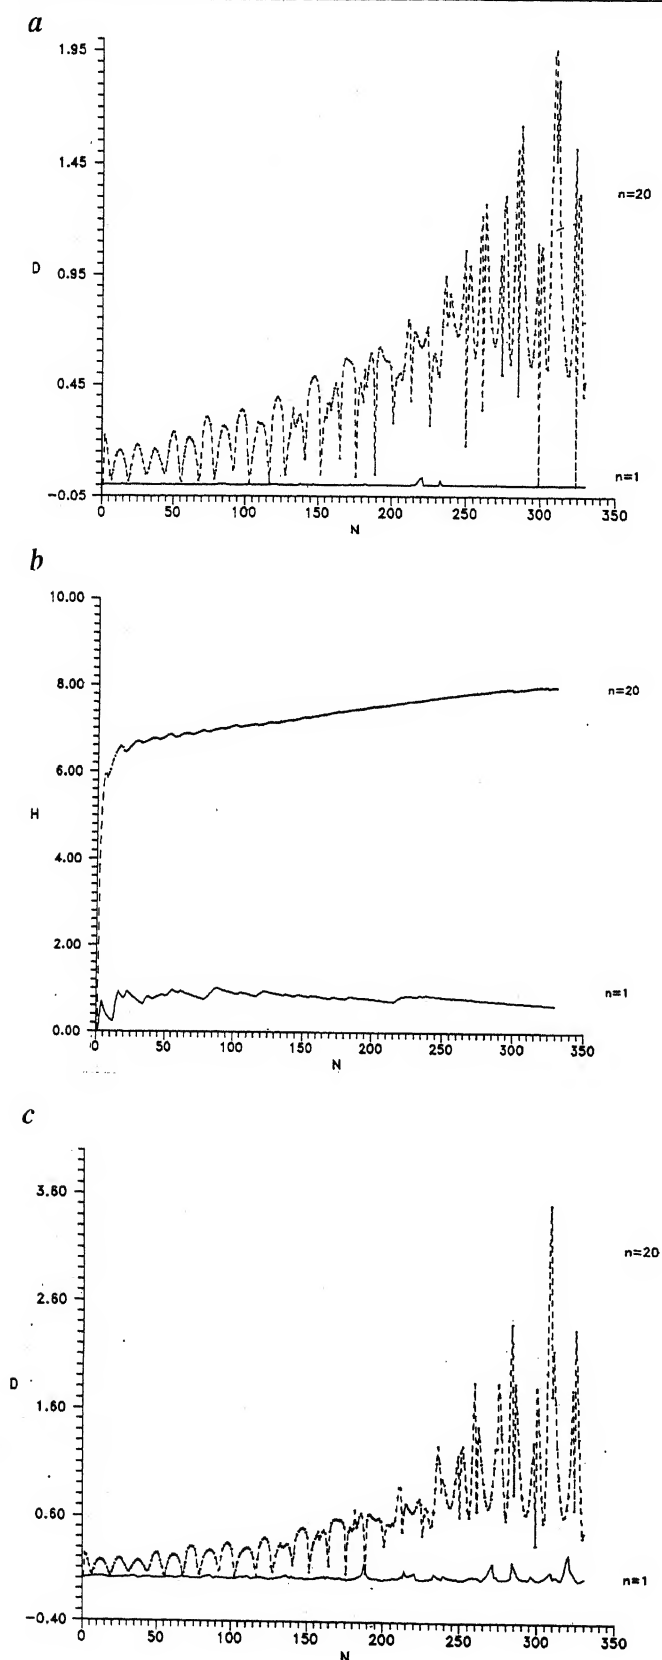

Figure 4a-c. Time evolution of phase space distance function D and KS entropy H in shifted particle position case (see text for details) for Rydberg atoms in external field: a, D for nonzero field relative to zero field; b, H associated with D in Figure 4a; c, D in nonzero field.

plots for shifted particle case are presented in Figures 4a-c. As before, Figure 4c is for the non-zero field case. Like the shifted wavepacket case, here also D remains more or less constant for $n=1$ and increases to a large value for $n=20$. The Kolmogorov-Sinai entropy initially oscillates around zero and then gradually approaches zero for $n=1$. For $n=20$ case H increases rapidly to a high positive value and then increases slowly via feeble oscillation. The negative slope in the former case *vis-à-vis* the positive slope in the latter, towards the end of the simulation, provides unmistakable signature of chaos in Rydberg atom in presence of external electric field. We have also studied (not shown here) the time evolutions of S , C , D and H for $n=5$ and $n=10$ states and also by using $F=2$. In general, for a given n , a higher value of F causes greater variations in the temporal profiles of these quantities. On the other hand, for a given F , a state with larger n value suffers more in comparison to little or no effect on a state with smaller n value. Since it requires too much of computer time we could not pinpoint the critical F value, for a given n , to exhibit the onset of chaos. In a nutshell F and n are considered to be two parameters of the present problem whose continuous variations and the associated dynamics are not studied. We have also obtained more or less similar results (not shown here) when a hydrogen atom in various electronic states experiences the time-dependent external Coulomb field due to a proton approaching for a head-on collision. It is important to note that the present short time simulation is inadequate in getting insights into the long-time asymptotic behaviour and hence one cannot infer with certainty about the final state and ionisation of the system as well as quantal suppression of chaos³⁷, if any.

In summary, we have shown that the quantum potential theories are helpful in studying the chaotic dynamics of a typical quantum system. Temporal evolution of Shannon entropy and correlation function has easily differentiated the regular and chaotic behaviour of hydrogen atom respectively in ground state and in a Rydberg state in presence of an oscillating electric field. Sensitive dependence on initial conditions is understood through time variation of phase space distance and the associated Kolmogorov-Sinai entropy. Further studies related to variations in n , F , ω , the atom, the nature of the external field, the time limit, etc. are in progress.

Reduced uptake based zinc resistance in *Azospirillum brasilense* sp7

P. Mangala Gowri and Sheela Srivastava

Department of Genetics, University of Delhi, South Campus, Benito Juarez Road, New Delhi 110 021, India

Zinc resistant *Azospirillum brasilense* sp7 exhibited a low affinity for the metal. A zinc-sensitized, streptomycin-resistant variant and a sensitive mutant of the parent strain showed an increased affinity for zinc. Both the affinity for, and uptake of the metal were in the order of parent strain < sensitised variant < sensitive mutant, suggesting reduced uptake as the mechanism of resistance to zinc. Neither magnesium nor manganese could bestow any protection against zinc toxicity in the sensitive mutant, suggesting a specific pathway for the entry of the metal.

THE presence and buildup of metal pollutants in the soil affects the soil microflora, which encompass the beneficial microorganisms, like the biological nitrogen fixers or BNFs. It has been reported that the total output of BNFs could be reduced in the presence of a metal ion¹. One such nitrogen fixer is the gram negative *Azospirillum brasilense* sp7, which has gained importance owing to its non-obligate association with grasses. This bacterium expressed a high level (10 mM) tolerance to zinc (Zn) which was constitutively expressed². Continuing to work with the same strain (referred to as the parent strain hereafter), the mechanism of Zn resistance has been studied in the bacterium and is presented in this paper.

The minimal nutrient medium (MM) and culture conditions for *A. brasilense* sp7 were as mentioned earlier². A streptomycin-resistant variant, MS12, was derived with a reduced maximum tolerable concentration³ (MTC) of Zn of 2 mM. This mutation seems to be of a multifold importance in azospirilla.

A. brasilense sp7 has been known to be recalcitrant to mutagen treatments. For the members of the Azotobac-

RESEARCH COMMUNICATIONS

teriaceae, a soil treatment method⁴ has been suggested to overcome a similar difficulty⁵. The cells of the parent strain were, therefore, subjected to soil treatment to obtain a strain amenable to mutagenesis⁶ (i.e. with 5 times less DNA than the parent strain owing to the reduced size of the treated cells). The derived strain was subjected to sequential *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG) mutagenesis (50 and 100 $\mu\text{g/ml}$) for 10 min in citrate buffer (pH 5.5). The mutagen was removed by centrifugation and the cell pellet suspended in normal saline was spread after appropriate dilutions. This resulted in three Zn^{S} (MTC 0.5 mM) mutants able to grow only in the presence of casamino acids. One of them, ZS2, was selected for further studies. This mutant retained the ampicillin resistance of the parent strain, and did not revert to either prototrophy or Zn resistance (frequency less than 1.6×10^{-10}).

The strains obtained were maintained as pure cultures raised from a single colony and the purity of the strains was checked periodically by testing antibiotic resistance markers, plasmid profiles, motility, cell morphology and growth on a defined medium.

In order to study the interaction of Zn with two commonly occurring divalent cations in the medium, Mg and Mn, competition experiments were conducted in the strain ZS2. 1 M stock of metal salts was prepared. Against a constant 1 mM Zn concentration, a range of Mg and Mn concentrations was tried. All the cations were added in the required amounts in the sterile MM (+0.2% casamino acids) before inoculation. Initial (0 h) and final (24 h) growth was recorded in reference to the absorbance at 560 nm. Uptake experiments were performed with ^{65}Zn (Bhabha Atomic Research Centre, Trombay, Bombay, India) at a concentration of 0.01 $\mu\text{Ci/ml}$ (0.005 $\mu\text{Ci}/\mu\text{mol}$) with a final, 2 mM Zn concentration. The assay proper was done in MM (or +casamino acids for ZS2) as described by Tynecka *et al.*⁷, except that the washing was done with MM containing 5 times Zn concentration used for assay. For determination of K_m and V_{max} , uptake was recorded after 30 min of ^{65}Zn addition, with a range of external Zn concentrations. Protein was extracted by subjecting 3 ml of culture to sonication in Vibronics Ultrasonic Processor P2 with the small probe. Three pulses of 15 sec each with an equal interval between the pulses were given. The amounts of protein were estimated by Bradford's protocol⁸ with bovine serum albumin as the standard.

No growth of ZS2 was observed in the presence of Zn with increasing concentrations of either Mg or Mn (Figure 1). Other divalent cations like cadmium, cobalt, copper, etc. could not be tested as the parent strain did not resist these metals. Also Mg^{2+} and Mn^{2+} are known to be the main competitors for Zn^{2+} in bacteria⁹⁻¹¹. However, the response of ZS2 to Zn in the presence of Mg/Mn indicated that perhaps Zn has its specific pathway, as reported for *Escherichia coli* K12 (ref. 12).

Figure 1a, b. Effect of divalent cations on the growth responses of ZS2 to Zn. Growth of ZS2 in the absence (●) and presence (○) of 1 mM Zn. Mean values \pm S.E.M. are plotted. Varying concentrations of (a) $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ and (b) $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ used.

The uptake pattern by *A. brasilense* sp7, variant MS12 and ZS2 is depicted in Figure 2. The behaviour of

Figure 2. ⁶⁵Zn uptake in the parent strain (●), variant (▼) and the Zn^S ZS2 (■). Bars indicate ±S.E.M.

strains MS12 and ZS2 is suggestive of the reduced uptake of Zn²⁺ being the mechanism of resistance in the parent strain. The degree of sensitivity, qualitatively, was directly proportional to the amount of Zn intake. That uptake of the metal in *A. brasilense* sp7 did not involve its accumulation has been proved earlier². Reduced uptake of a metal, as the mechanism of resistance, is known in several bacterial species, e.g. for Cd²⁺ in *Staphylococcus aureus*^{7,13}, *Bacillus subtilis*¹⁴, for Cd²⁺ and Zn²⁺ in *Pseudomonas putida*¹⁵, and for CrO₄²⁻ in *P. aeruginosa*¹⁶. The response of *A. brasilense* sp7 thus conforms to this general trend in several bacteria.

While the uptake stabilized within 10 min of Zn exposure in *A. brasilense* sp7, both the variant and the sensitive mutant exhibited influx till about 30–40 min of exposure. At the maximum levels of uptake, the fold accumulation of the metal by the strain sp7, MS12 and ZS2 was found to be 3.08, 4.60 and 6.90, respectively, given the intracellular volume of water as 2.2 μl/mg proteins for *A. brasilense* sp7¹⁷.

Bacteria exhibiting obstructed or restrained uptake of the metal as the resistance mechanism show a low affinity for the metal. A consequent increased affinity in sensitive strains has been regularly observed^{7,14}. The K_m and V_{max} values calculated from Lineweaver Burk plots for all the three strains in this study followed the same

Figure 3. Double reciprocal plot for Zn uptake in strains sp7 (○), MS12 (●) and ZS2 (▼).

Table 1. The affinity for Zn²⁺ of the three strains and rates of metal uptake in *A. brasilense*

Strain	K_m (mM)	V_{max} (μmol/min/mg protein)
<i>A. brasilense</i> sp7	—	—
MS12	10.0	3.3
ZS2	2.85	13.3

pattern (Table 1) as known in other systems. The sensitive strains followed the Michaelis-Menten saturation kinetics, while the Zn-resistant parent strain failed to exhibit the saturation, similar to the observation in *B. subtilis*^{14,18}. The reciprocal plot constructed for the latter was, thus, unusual (Figure 3). We have concluded that *A. brasilense* sp7 exhibited a lack of affinity for Zn and this results in rendering the organism resistant. We assign this lack of affinity towards Zn²⁺ due to a typical response exhibited by sp7 cells in the presence of the metal. As reported by us earlier, the cells get enlarged, show an increased level of exopolysaccharides over control and release a melanin-like pigment³.

Though the data on metal resistance in azospirilla are available, they are preliminary and sparse^{19,20}. In this

investigation, efforts have been made to unravel the mechanism of resistance to Zn in this hitherto unexplored organism as a step towards effective biofertilizer application. This study also fulfils the need to understand the effect of arbitrary application of metal-containing pesticides on numerous non-target microorganisms. The efficacy of Zn^r *A. brasilense* when applied to maize seeds in *in vitro* studies has already been established in our laboratory²¹.

Ammonia volatilization and denitrification losses from nitrogen fertilized flooded soil as affected by the addition of iron pyrites

D. Blaise*, A. Amberger and S. von Tucher

Institute of Plant Nutrition, TU-Munich-Weihenstephan, D-85350 Freising, Germany

*Central Institute for Cotton Research, GPO Bag 225, Nagpur 440 001, India

Results of a laboratory study indicated that iron pyrites reduced nitrous oxide (N₂O) and NH₃ evolution from flooded soil fertilized with KNO₃ or urea. Total gaseous (N₂O + NH₃) loss was reduced by 47.3% with the addition of pyrite compared to the urea alone treatment.

GASEOUS N loss through NH₃ volatilization and denitrification is responsible for the low N use efficiency of rice under flooded conditions¹. Nitrification² and urease inhibitors³ and slow-release fertilizers⁴ are proposed as strategies to reduce N loss and enhance NUE. Nitrification inhibitors reduce losses through denitrification^{5,6} but have been found to accentuate NH₃ loss⁷. Iron pyrites, a mineral occurring in plenty as sedimentary deposits in parts of Bihar, India, have been found to inhibit

nitrification⁸ and reduce NH₃ loss from surface-applied urea⁹. Since pyrites retard nitrification, it could possibly reduce denitrification. Hence, an incubation study was conducted in the laboratory to find out the effect of pyrite on denitrification and NH₃ volatilization from urea applied to a flooded soil.

Surface soil (0–15 cm) from cultivated fields of Duerast, Freising, Germany, having pH 6.8 (soil:CaCl₂ 1:2.5), organic C 1.12%, 4.1 mg NH₄⁺-N and 15.6 mg NO₃⁻-N kg⁻¹ soil, total N 0.12% was used in the study. Air-dry soil (200 g) was placed in 500 ml jars. The soil was flooded to a depth of 2 cm and pre-incubated for two weeks. To enhance the reduced conditions, glucose solution equivalent to 500 mg C kg⁻¹ soil was applied. The mineral-N status of soil after pre-incubation was 6.3 mg NH₄⁺-N and 0.1 mg NO₃⁻-N kg⁻¹ soil. After the pre-incubation, the soils were treated with N at the rate of 100 mg kg⁻¹ soil in the form of KNO₃ and urea solution, separately, with or without pyrite. Pyrites, obtained from Pyrites and Phosphates Chemicals Limited (PPCL) New Delhi, was added equivalent to 100 mg S kg⁻¹ soil. Each treatment combination was replicated thrice. A no N control was also maintained. The jars were covered with a lid provided with a rubber septum. The sides of the lid and rubber septum were sealed with silicone to prevent gas leaks. After 1, 2, 3, 5 and 7 days, gas samples were taken and analysed for N₂O-N by gas chromatography (Varian 3400) using an electron capture

Table 1. Effect of pyrite on NH_3 loss from urea applied to a flooded soil ($20 \text{ mg urea-N } 200 \text{ g soil}^{-1} \text{ jar}^{-1}$)

	Days			Total
	1	2	7	
	(mg $\text{NH}_3\text{-N jar}^{-1}$)			
Urea	$0.62 \pm 0.078^*$	0.46 ± 0.024	0.41 ± 0.019	1.49 ± 0.104
Urea + pyrite	0.53 ± 0.016	0.36 ± 0.046	0.054 ± 0.0034	0.94 ± 0.062

*Standard error.

**Figure 1.** Effect of iron pyrite on nitrous oxide evolution from flooded soil (O, KNO_3 ; ●, KNO_3 + pyrite; Δ, urea; ▲, urea + pyrite). Vertical bars indicate standard error; LSD ($P < 0.01$) = 0.73 for day seven.

detector. For estimating NH_3 loss, a separate set of jars of each treatment in triplicate was set up similar to the previous one. The jars in this case were covered with parafilm provided with a few micropores for aeration. The NH_3 evolved was trapped in 4% 10 ml boric acid-mixed indicator solution contained in vials placed at the soil surface⁹. The trapped NH_3 was estimated by titrating with H_2SO_4 (0.005 N).

By day 5, almost the entire applied N was recovered as $\text{N}_2\text{O-N}$ with KNO_3 -treated soils (Figure 1). Addition of pyrite resulted in lower N_2O evolution. At the end of 7 days, amount of $\text{N}_2\text{O-N}$ recovered was 34.5% of ap-

plied N with KNO_3 + pyrite treated soils compared to KNO_3 alone treatment. Under reduced conditions, nitrate is known to be rapidly denitrified¹⁰. On the other hand, urea-treated soils had low N_2O evolution. Most loss occurred between fifth and seventh day. The slow urea hydrolysis¹¹ and nitrification^{12,13} processes under flooded conditions are responsible for the initial lag period observed with the urea-treated soils. Urea + pyrite-treated soils had less than half the N_2O evolution compared to urea alone treatment. This could be due to the nitrification inhibitory effect of pyrite⁸. But we observed that the inhibitory effect of pyrite is rather very low in flooded soils. The most plausible reason appears to be that pyrite is directly involved in inhibiting nitrite- or nitric- or $\text{NO}_3^- \rightarrow \text{NO}_2^- \rightarrow \text{NO} \rightarrow \text{N}_2\text{O} \rightarrow \text{N}_2$ nitrous oxide reductases. This is very much evident from the low N_2O evolution observed with KNO_3 + pyrite treatment. Kowalenko¹⁴ reported S anions to reduce denitrification loss, which suggests that the sulphides in iron pyrites could play a major role in the process. The other possible explanation could be that as NO_3^- becomes limiting, N_2O is used as an electron source reducing it to N_2 (ref. 15).

Ammonia volatilization was observed only in the urea-treated soils (Table 1). NH_3 evolution was observed right from day one, which declined later possibly due to it being nitrified or adsorption by the soil¹³. Addition of pyrite reduced NH_3 loss from urea by 37%. This is attributed to the acidic nature of pyrite¹⁶ preventing the rise in floodwater pH⁹. Total gaseous-N ($\text{N}_2\text{O} + \text{NH}_3$) loss was 3.49 mg jar^{-1} for the urea alone treatment which was brought down to 1.85 mg jar^{-1} with the addition of pyrite, a reduction of 47.3%. The results also indicate the NH_3 volatilization and denitrification losses to be interdependent¹⁷. The possibility of losses beyond 7 days cannot be eliminated. However, earlier studies^{18,19} showed maximum loss to occur within first 10 days.

From the results of this study it is not clear whether pyrite reduces total denitrification as the other NO_x components could not be analysed. The effect of pyrite on denitrification, therefore, needs to be probed further. However, it does offer a benefit by way of reducing NH_3 loss and N_2O evolution which is implicated in the depletion of stratospheric ozone layer.

Biological control of blast disease of fingermillet (*Eleusine coracana* L.) and an analysis of fertility of *Magnaporthe grisea*

Viji Sittther and S. S. Gnanamanickam

Centre for Advanced Studies in Botany, University of Madras, Madras 600 025, India

Six strains of fluorescent pseudomonads which belong to *Pseudomonas fluorescens* and *P. putida* were screened in the laboratory for their ability to inhibit the ragi blast fungus *P. grisea*. The bacterial strains showed fungal inhibition in dual plate assays in the laboratory and reduced ragi blast severity in the field. Leaf and neck blast were reduced by 45.3 to 65.2% and 24.3 to 54.9% in moderately resistant ragi cv. CO-7 and by 59.1 to 72% and 33.3 to 63.3% respectively in the susceptible cv. PR-202. *P. fluorescens* strains 7–14 was most effective amongst the bacterial treatments. For the first time, perithecial formation occurred in 11 of the 96 *P. grisea* combinations when they were mated in the laboratory with known testers of rice blast fungus which were used as a parent.

FINGERMILLET (*Eleusine coracana* L.) commonly known as ragi ranks second in importance among the millets in India and is widely cultivated in several parts of Tamil Nadu, Andhra Pradesh, Karnataka and Maharashtra. Blast incited by *Pyricularia grisea* (Cke) Sacc, is one of the major destructive diseases causing excessive damage to this crop from seedling to earhead-forming stages.

The disease occurs during all growing seasons and on almost all ragi varieties cultivated.

Considering the hazards of chemical applications, biological control has emerged as an important alternate strategy for disease control in recent years. There has been much success in biological control of crop diseases by using antagonistic bacteria of the fluorescent pseudomonad group^{1–3}. Studies have revealed the potential of antagonistic microorganisms in inhibiting pathogens at the root–soil interface, thereby protecting perennial and annual plants such as cotton, potato, tobacco, wheat and rice^{4–7}. Thomoshow and Weller⁸, Weller and Cook⁹ and Schippers *et al.*¹⁰ found these microorganisms to inhibit pathogens by producing antibiotics, siderophores (compounds that chelate biologically available iron) and plant growth-stimulating substances. Earlier studies from our laboratory have shown that, when carefully selected strains of *Pseudomonas fluorescens* or *P. putida* were used as bacterial treatments, such treatments resulted in the reduction of blast, sheath-rot and sheath blight severities in rice^{11–15}.

The discovery of the sexual stage¹⁶ in *P. grisea* has broadened the understanding of genetic variation in the genus *Pyricularia* and is important for effective blast disease management, as resistant breeding strategies are based on the clonality of the pathogen. Complexity of fertility in this fungus is partially responsible for incompatibility amongst isolates. The purpose of the present fertility studies is to determine the sexual compatibility of the Indian isolates of *P. grisea* when mated with fertile testers. We have evaluated a selected set of fluorescent pseudomonads for the suppression of ragi blast in the laboratory and in the field.

Strains of fluorescent pseudomonads, *P. fluorescens* Pf KE26, Pf TNC82, Pf 7-14, Pf Pfcp and *P. putida* Pp U113b, and Pp V14i isolated in our laboratory were used in the present study. Infected finger millet tissues were collected from the South Indian states of Tamil Nadu, Andhra Pradesh, Kerala and Karnataka from 1993 to 1995 and 96 monoconidials of *P. grisea* were isolated.

Crosses between 24 ragi isolates and four rice isolates (testers), GY-11, KA-3, KA-7 and KA-9 (obtained as gift from J. L. Notteghem, CIRAD, Montpellier, France) were made by placing mycelial agar blocks of the paired isolates about 5 cm apart from each other on oatmeal agar plates. The petri dishes were incubated at 27°C for about a week and then transferred to 22–24°C under continuous illumination. Fertility of these strains was monitored by observations on perithecial formation.

For *in vitro* assay of antibiosis, 10 ml of sterile water was poured into slant cultures of *P. grisea* and the surface of mycelial growth scraped. This suspension was spread on PDA plates and air-dried. Fresh bacterial cell suspensions that contained 10^9 colony-forming units/ml were prepared from 24 h grown bacterial cultures raised on Kings' B medium and were spotted at the centre of the plates using sterile toothpicks. Plates without bacterial inoculation served as control. Antifungal activity was determined by measuring the diameter of inhibition zones. Three replications were maintained for each bacterial strain evaluated.

Two field experiments and one seedbed experiment were conducted at three different locations during 1993 to 1995. The field experiments were conducted at Anna University, Madras and at Pallikaranai, a suburb of Madras. The seedbed experiment was made at the Regional Agricultural Research Station, Pattambi, Kerala which is a hot-spot for the disease. Ragi seeds (CO-7 and PR-202) obtained from the University of Agricultural Sciences, Hebbal, Bangalore were used for the study. Seeds for the field experiments were sown in a randomized complete block design (RCBD) with three replications in field plots of 1.5 × 1.0 m. The fungicide tricyclazole (beam) was also included as a treatment for making comparisons. Two most efficient strains that afforded maximum disease control in the first experiment were selected and evaluated in the seedbed experiment. For the seedbed experiment, seeds were sown in 1 m wide rows and were maintained in upland condition.

Bacteria were grown in King's B medium broth for 24 h and the cultures were adjusted to an OD of 0.1 at 600 nm with 1% w/v carboxymethylcellulose (cmc) to obtain a cell concentration of 10^9 cfu/ml. Surface-sterilized seeds were soaked in the bacterial suspension for 12 h at 28°C and air-dried. At the time of sowing, seeds had a 10^9 cfu (colony forming units) per gram. Likewise, seeds were treated with the fungicide at the

concentration of 2 g a.i./kg seed. Seeds treated with sterile cmc served as check. Besides seed treatment, plants were given foliar sprays with the bacteria or fungicide on 15, 25 and 35 days after sowing. Fungicide was sprayed at a concentration of 400 g a.i./ha. Plants were inoculated with the blast pathogen on the 36th day. For artificial induction of blast, *P. grisea* inoculum was raised on a medium that consisted of sterilized grass leaves (15 g) and sucrose (2 g). After 15 to 20 days, the spores were dislodged and the spore concentration was adjusted to 50,000 conidia/ml in 0.5% gelatin solution according to the method of Mackill and Bonman¹⁷ and sprayed. Disease was scored by random examination of 15 plants per plot for leaf blast and 25 plants for neck blast. Disease was scored in the 0 to 5 scale developed by the All India Co-ordinated Small Millets Improvement Project. Leaf blast severity index (LBSI) and percent disease reduction were calculated and the data subjected to statistical analysis.

Perithecial formation was observed in 11 of the 96 crosses made. Mature perithecia were formed at the intersection of growth of the fertile and compatible isolates after 28–32 days. They occurred singly or in groups and were partially embedded in the medium with long beaks protruding from the agar surface. The release of asci from a mature perithecium is shown in Figure 1.

All the six bacterial strains inhibited the growth of *P. grisea* *in vitro*. The bacterial strains differed in their ability to inhibit the different isolates of *P. grisea* and induced inhibition zones varying from 10 to 33 mm in

Figure 1. Release of asci from a mature perithecium produced in the laboratory. Mature perithecia were formed by *P. grisea* isolates pathogenic to finger millet when they were mated with known tester isolates of *P. grisea* pathogenic to rice. The testers were obtained from J. L. Notteghem, France²².

Figure 2. Dual plate assay that shows the inhibition of *Pyricularia grisea* by *Pseudomonas fluorescens* Pf 7-14 on a PDA plate. Such assays are used in the laboratory for locating efficient antagonists.

Control	350	10	2.10	1.78	290
			LSD $r = 0.67$ (0.05) = 13.2 (0.01) = 18.3		

Figure 3. Biological suppression of finger millet of blast by *Pseudomonas fluorescens* Pf 7-14 in cv. PR-202 plants. Bacteria were applied as seed treatment and as three additional foliar sprays. Leaf blast was induced by artificial inoculation of *Pyricularia grisea*. Finger millet leaves on the right are from bacterial treatment and they show substantial reduction of leaf blast. On the left are finger millet leaves from untreated control plants.

diameter. Strains Pf KE-26 and Pf 7-14 afforded maximum inhibition zones of 30 and 33 mm diameter against *P. grisea* isolate 21.1.2 (Figure 2). Strains Pf TNC-82, Pf Pfcp and Pp v14i showed maximum inhibition against isolate 19.1.1 (24, 27.5 and 19 mm) respectively.

Data on suppression of blast afforded by the bacterial strains in the field tests are given in Tables 1 and 2. In field experiment 1, leaf blast control ranged from 45.3 to 65.2% and neck blast from 24.3 to 54.9% with bacterial treatments while in the second, 59.1 to 72% reduction in leaf blast and 33.3 to 63.3% reduction in neck blast were observed (Table 1). The fungicide tricyclazole proved superior in controlling blast in both the varieties tested. Figure 3 shows the substantial reduction of leaf blast afforded by Pf 7-14. There was a significant increase in total grain yield and 1000 grain weight due to bacterial treatments (Table 2). When two of the most efficient *P. fluorescens* strains Pf 7-14 and Pf Pfcp were evaluated further in seedbed at Pattambi, Kerala, these strains reduced leaf blast by 69.1% and 63.2% while the systemic fungicide reduced leaf blast by 72.9% (Table 3). There was no significant increase in total grain yield.

Table 3. Effect of bacterial treatments with *P. fluorescens* strains (Pf 7-14 and Pf Pfcp) on leaf blast reduction and yield in ragi cv. PR-202 seedbed experiment, Pattambi, Kerala

Treatment	Leaf blast		Grain yield (g)*
	Percent incidence	Percent control

Control	74.9	0.0	300
LSD			
(0.05) = 4.2			
(0.01) = 6.4			

*LSD analysis not significant.

Our results from *in vitro* studies, field trails and seedbed experiment show the efficacy of fluorescent pseudomonads in suppressing the growth of *P. grisea* and the development of ragi blast. The difference in the zones of inhibition with the various pathogen isolates could be due to the variance in virulence amongst *P. grisea* isolates. Fravel¹⁸ observed that the parameters affecting the production of secondary metabolites could modify *in vitro* antibiosis. There was good correlation between *in vitro* antibiosis and disease reduction. Similar results have been reported earlier¹⁹⁻²¹. Amongst the bacterial treatments, strain of 7-14, a proven biocontrol agent afforded most leaf and neck blast control. Though disease control afforded by bacteria was not equivalent to that afforded by tricyclazole, there was a significant reduction in disease with the bacterial treatments (Table 1).

The potential of *Pseudomonas* spp in suppressing rice blast when applied as seed bacterization and as additional foliar sprays has been previously demonstrated¹⁴. In the study conducted by Gnanamanickam *et al.*¹² at the International Rice Research Institute (IRRI), Philippines, it was shown that fluorescent pseudomonads reduced rice blast severity when applied as seed treatment and foliar sprays. Several reports have suggested that antibiotics produced by *P. fluorescens* strains play an important role in disease suppression^{5,8,11,14,18}.

Formation of perithecia by *P. grisea* isolates pathogenic to ragi has not been observed in India. The sexual stage usually does not occur in the field. With the help of known tester isolates²², we have been able to observe the sexual stage of the blast fungus, *Magnaporthe grisea* (Figure 1). With the help of this genetic tool, it is possible to study the genetics of pathogenicity or virulence of the Indian isolates of *M. grisea* towards ragi and rice.

From this study it is clear that bacterial strains can be efficiently used to control blast when used as seed treatment and foliar sprays. The results of bacterization

with fluorescent pseudomonads are encouraging. The present study suggests that carefully selected strains *P. fluorescens*/*P. putida* can be developed as biological formulations for field-level application by our resource-poor farmers for effective management of ragi blast. With the observation that the ragi strains are fertile and produce the sexual stage, *M. grisea* in laboratory crosses with known testers of rice, the genetics of virulence in *M. grisea* towards ragi and rice can be established and we are pursuing this at present.

ACKNOWLEDGEMENTS. We thank Prof. A. Mahadevan, Director of the Centre for Advanced studies in Botany for providing laboratory facilities, Prof. V. P. S. Dev of Kerala Agricultural University at Pattambi for providing field space. Space provided by Anna University and Pallikaranai farms for conducting experiments is gratefully acknowledged. We acknowledge the funding provided by Rockefeller Foundation in the form of research grants to support our work on the biological control of blast.

Received 26 March 1996; revised accepted 30 May 1996

Discovery and invention

Sir Martin Rees

In Victorian times, the national scientific enterprise was minuscule by today's standards. Yet the commitment to the public understanding of science was not. The marvellous national and civic museums – cathedrals of discovery and invention – consumed large resources by the standards of that time. Our forebears believed, as fervently as the British Association does now, that the UK's achievements in science, engineering, and technology deserve wider appreciation, that science is part of our culture, and that how it is applied should concern us all.

The 'public' for science

Science and engineering had a high profile. Most people have heard of the great nineteenth century engineers – Brunel, Telford, and so forth. It is actually harder to name living engineers even though their marvels surpass those of earlier centuries. And it was not just the practical men – the 'wealth creators' – who earned public acclaim. Think of Darwin: his insights had no practical payoff, but he was a revered figure because he changed the way humans see their place in nature.

So what about public attitudes today, as we approach the twenty-first century? We have all read the outcome of scientific quizzes, in newspapers and elsewhere, which reveal that many can hardly tell a proton from a protein. Such people can (partially) excuse themselves by claiming that the facts in themselves are not the essence. What matters is having a rough 'intellectual map': so that we can appreciate our natural environment; so that the artefacts that surround us do not seem mysterious; and so that we can all participate, critically, in shaping how technologies are developed and applied.

Everyone needs a basis for assessing when scientific claims are credible and when they are not. Noisy controversy does not always signify evenly balanced arguments; but most issues that rightly concern us involve genuine scientific uncertainties, and major trade offs. The ethical and social implications of (for instance) *in vitro* fertilisation from foetuses, genetic screening, or environmental degradation can and should be widely appreciated and discussed, even by people who do not understand (and may not be specially interested in) the science *per se*.

The adult public is very heterogeneous. All of us are part of it. Professional scientists are depressingly 'lay' outside their specialisms – I depend on 'popular' presentations in the media for updates on biomedical topics. Broadcasts or newspaper articles about my own professional interests deepen my respect for journalists who successfully cover all the sciences, working to tight deadlines. I know, from experience, how hard it is to explain non-technically, even something in my specialist field.

Science generally earns a newspaper headline, or a place on the TV bulletins, only as a background rather than as a story in its own right. Indeed, coverage restricted to 'newsworthy' items – newly announced results that carry a crisp and easily summarisable message – cannot avoid distorting how science develops. Scientists cannot reasonably complain about this any more than novelists or composers would complain that their new works do not make news bulletins. The place of science is in features, documentaries, and so forth rather than news.

A recent *Daily Telegraph* poll asked people on what topics they would like to see more newspaper coverage. Top choice was medicine; science and invention tied with crime for second place.

Within science, it is often the utterly 'irrelevant' subjects that fascinate people most. Dinosaurs have topped the charts since Richard Owen announced their discovery at the British Association

in 1841. Cosmology runs dinosaurs close; so does human origins. Despite an intellectual climate where some scientific advances arouse unease, these subjects have retained a positive and non-threatening image.

Communicating science: a researcher's perspective

Researchers do not usually shoot directly for a grand goal. Unless they are geniuses (or unless they are cranks) they focus on 'bite sized' problems that seem timely and tractable. That is the methodology that pays off. However, it carries an occupational risk – we may forget that we are wearing blinkers and that our piecemeal efforts are only worthwhile insofar as they are steps towards some fundamental question. The physicist Arno Penzias, who made a really great discovery, said that he did not himself appreciate its full significance until he read a 'popular' description of it in the *New York Times*. Presenting our work as clearly as we can to general audiences, who do not care about the details, helps us to see it in perspective. (Niels Bohr said that you should speak as clearly as you think, but no more so. That is a good maxim – though Bohr himself apparently took caution to excess by mumbling inaudibly and incomprehensibly!)

Another salutary question for scientists is this: if you could inject one idea from your subject into 'common culture', what would it be? I should choose cosmic evolution.

At British Association meetings in the 1860s, Darwin's ideas were boisterously debated; they were part of the nineteenth century culture. He showed (to quote the famous final words of the 'Origin of species') how, 'whilst this planet has been cycling on according to the fixed law of gravity, from so simple a beginning, forms most wonderful... have been, and are being, evolved'. Cosmologists now go back before Darwin's 'simple beginning'. They view our entire solar system in a broad evo-

Sir Martin Rees is in the Institute of Astronomy, Madingley Road, Cambridge CB3 0HA, UK.

lutionary context, stretching back to when the Milky Way galaxy first formed – right back, even to the hot dense fireball from which our entire universe emerged.

When a star explodes as a supernova, astronomers and physicists study it eagerly. Yet why should anyone else be interested in exploding stars thousands of light years away? The answer is that they hold the answer to the question 'where did the atoms we are made of come from?' Were it not for supernovae, none of us (nor even the earth) could exist.

Stars and nebulae contain roughly the same proportions of the different chemical elements as our solar system. What determines this universal mix? Did a creator turn 92 different knobs? The answer is no. Atoms on earth were forged by nuclear fusion in ancient stars that exploded as supernovae somewhere in the Milky Way. The atoms then found themselves in an interstellar cloud that condensed into new stars, some with retinues of planets. One of these stars was our sun. We can calculate the resultant 'mix' – why carbon and oxygen are common, but gold and uranium are rare. Galaxies are like vast ecosystems, in which pristine hydrogen is recycled through successive generations of stars, gradually building up the entire periodic table.

That link between us and the stars is just an example of the kind of concept that I should like to be part of the broader culture. It stimulates, of course, another question: where did the hydrogen itself come from? The answer itself lies in the initial big bang which set our entire universe expanding – another (more uncertain) story. However, it leads into my next topic, the scope and limits of science.

Hierarchy of sciences

Claims to understand anything about the early universe might seem presumptuous, but cosmology is actually one of the more tractable sciences. Inside a star (and in the early universe) conditions are so extreme that everything is broken down into its atomic constituents, and governed by simple laws. Moreover, the laws of physics are universal: atoms in remote galaxies and at early cosmic epochs obey the same laws as those we

study in the laboratory. It is complexity that makes things hard to understand, not size. Understanding a frog is a far more daunting intellectual challenge than anything confronting cosmologists.

The atoms that made the young earth are stardust – to have understood this is a triumph of twentieth century science. However, elucidating how those atoms combined, via Darwinian selection, into progressively more intricate forms, and eventually into creatures that could ponder their origin, is an unending quest that has barely begun. This perspective should caution us against scientific triumphalism – against exaggerating how completely we will ever understand anything really complex. The different sciences are in a hierarchy – in the complexity of the things they deal with – with physics at the base and (I suppose) psychology at the apex. But that does not mean that the other sciences are applications of physics. Every science, from chemistry to social psychology, has its own irreducible concepts, based on the emergent properties of complex systems. In understanding turbulence, analysing the fluid in atoms does not help. What goes on in a computer could be described in electrical terms, but that misses the essence, the logic encoded in those signals. We cannot solve Schrödinger's equation for any biological system, but even if we could, it would never yield an economical description or insight.

There is a sense – but a limited one – in which some sciences can claim to be especially 'fundamental'. Causal chains – if you go on asking why? why? – lead back to a question in particle physics or cosmology. These subjects relate to deep aspects of reality. We pursue them for the stimulus they pose (to theorists and instrumental innovators alike), and because the breadth has proved a fruitful policy – not because the rest of science depends on them. The sciences are not in a hierarchy whose superstructure is imperilled by an insecure base.

Status of scientific ideas

The way we approach science, what problems strike us as interesting, what styles of explanation are culturally appealing, and (more mundanely) what fields attract funding depend on a range

of political, sociological, and psychological factors. Some projects, especially big international ones, are a by-product of activities driven by other imperatives. (For example, the exploding supernovae I mentioned above would be less well understood were it not for the space programme, and supercomputers.)

It is important, as well as enlightening, to appreciate how pervasive these social and political factors are. The behaviour of scientists, and the external influences on their community, offer fascinating topics for study. However, for us 'in the zoo' science itself advances, albeit fitfully, towards a culture independent outcome. Steven Weinberg gives an apt metaphor:

A party of mountain climbers may argue over the best path to the peak, and these arguments may be conditioned by the history and social structure of the expedition, but in the end either they find a good path to the summit, or they do not, and when they get there they know it.

Why can we, seemingly, make some sense of the external world? Why can so much be described mathematically? Is mathematics itself a discovery, or an invention? These questions are for philosophers – they are deeper than scientists can professionally address. So let us turn to more concrete aspects of discovery.

Discoveries out of the path of imagination

Nearly 400 years ago Francis Bacon highlighted three astonishing discoveries – gunpowder, silk and the mariner's compass. In *Novum organum* he writes: 'These things... were not discovered by philosophy or the arts of reason, but by chance and occasion'; they are 'different in kind so that no preconceived notion could possibly have conducted to their discovery'. It was Bacon's belief that 'there are still many things of excellent use stored up in the lap of nature having nothing in them kindred or parallel to that which is already discovered... lying quite out of the path of imagination'.

So it was, most certainly, in the nineteenth century. X-rays, discovered just 100 years ago, must have seemed

fully as magical as the compass did to Bacon. Though of manifest benefit, they could not plausibly have been planned for. A proposal to make flesh appear transparent would not have got a research grant – even if it had, it surely would not have led to X-rays. It is easy to pick other examples. A nineteenth century project to reproduce music would have led to immensely elaborate pianolas or orchestrions, but would not have identified – still less accelerated – the technologies that actually achieved this goal.

Bacon contrasts his three 'magical' discoveries with the invention of printing, which 'has nothing in it which is not open and generally obvious... when it had been made, it seems incredible that it should have escaped notice so long'. Most innovations now emerge, as printing did, via Bacon's second route: 'from the transferring, composition and application of [things] already known'. What is remarkable, and indeed exhilarating, is that discoveries still take us unawares. There can still be scientific revolutions, despite the immense infrastructure of natural science that was quite lacking in Bacon's day, or even in the nineteenth century; indeed the lengthened frontiers of knowledge increase the chance of surprises.

I will focus below on some contemporary lessons that can be drawn from these distinctions, but will first make some general remarks on the creative impetus that drives any discovery or invention.

Creativity and individuality

Scientific insight needs concentrated effort and preparation. It also demands intuition and imagination. In this respect, it parallels artistic insight – equally an attempt to seek new patterns, and new perspectives on the world. However, those similarities should not obscure one glaring difference between the two enterprises, which stems from the interlocking, cumulative, and intensely social character of science.

In the arts, individuality shines through even at the amateur level. Everyone's contributions, even if soon forgotten, are personal and distinctive. Issues or priority do not arise, as they do in science. As Medawar noted, when Wagner took 10 years off in the middle

of the Ring cycle to compose the '*Meistersinger*' and '*Tristan*', he was not worried that someone would scoop him on '*Götterdämmerung*'.

In science, discoveries emerge when the time is ripe – they are contingent on some prior innovation, perhaps in another field. Individuals seldom make more than a few years' difference to when a particular advance occurs. There are exceptions – the laser for instance, or sociobiology – but in populous fields the key ideas are 'in the air', ready to be grasped. The greatest figures may, however (as Watson and Crick, for instance, did) help those ideas to gell neatly, rather than emerge untidily. What made Einstein unique in twentieth century physics is that he really did make a distinctive long lasting imprint: without him, we might have had to wait decades for equivalent insights on gravity.

Although their personal imprint may fade, scientists have the compensation that, if it survives critical scrutiny, their work endures as a brick in the edifice of 'public knowledge'. And they have a second compensation: literary critics are seldom also creative writers, but every researcher is, albeit in a small way, both a creator and a critic of the collective scientific enterprise.

These remarks about science, incidentally, are intended to embrace engineering and technology as well. Claims that 'academic' research demands mental processes of a specially elevated kind are baseless snobbery, of a kind that is thankfully dying out. There is at least as much innovation in the computer or pharmaceutical industry as in any field of basic research. Indeed, the intellectual leap in the concept of a zip fastener surpasses what most academics achieve in a lifetime.

Until the nineteenth century academic science (such as it then was) was only tenuously linked with practical innovation. Science and technology now have a complex symbiosis. Research triggers applications; but, equally, new techniques and instruments boost scientific discovery. If you look at what people do day by day, there may seem little difference between a biotechnology company and a university laboratory, not between someone in an aerospace company and someone innovating an instrument for space astronomy. These activities have something crucial in common: the work

is only worthwhile – it will only pay real 'dividends' – if it is really at the leading edge.

Forecasting and insight

In 1937 the American National Academy of Sciences organised a study aimed at predicting breakthroughs; its report makes salutary reading for technological forecasters today. It came up with some wise statements about agriculture, about synthetic gasoline, and synthetic rubber, but what is more remarkable is the things it missed. No nuclear energy, no antibiotics (though it was 8 years after Fleming), no jet aircraft, no rocketry nor any use of space, no computers; certainly no transistors. This committee overlooked the technologies that actually dominated the post-war era.

The pace of technological advance certainly is not slacking. Some everyday artefacts – laptop computers, camcorders, even supermarket barcodes – depend on basic science that dates back only 20 years or so. Likewise the new fields of biotechnology. A current attempt to predict future breakthroughs might have a 'hit rate' as dismal as the US forecasters achieved in 1937. The most dramatic and fruitful innovations will still surprise us. They will be the outcome of *some* new basic science, but of course we do not know what. Applications that are transforming the way we live were initiated by investments in basic research that were modest in relation to their impact. Some projects paid off colossally; others did not, but retrospective studies in the USA suggest that overall 'return' on basic research exceeds 20%.

On the football field, not everyone scores – you cannot predict who will, nor when. However, that does not mean that the other players are dispensable. Likewise, it is essential to maintain a broad science base, and a web of connections between different disciplines. Advances that deepen our understanding of some important aspects of nature – the physics of materials, living cells, or the environment – or even new mathematical ideas, are likely to find some application.

Obviously some fields are more likely to foster applications than others (I would concede that molecular biology is

a better bet than black holes in this regard!), but 'curiosity driven' research can impact in quite unexpected ways. For instance, it was studies of dust in interstellar space that led to the carbon structures known as fullerenes; and the exotic fauna on the ocean bed may seem as remote as outer space, but their ecology is relevant to the Brent Spar debate.

Nothing I have said, incidentally, is meant to disparage the Foresight exercise undertaken by the UK Government, whose agenda is less futuristic. The Foresight panels bring people together, forge new links that are themselves worthwhile, and will help the country to exploit what has already been discovered. A 'Foresight' strategy could do harm only if undue concentration on highlighted research areas led to a funding blight on others.

Climate for invention and discovery

The UK has a fertile record for 'leading edge' discovery and invention. Can we enhance it – can we at least ensure that we do not slide relative to others? and can we exploit our discoveries better?

'A society organised to allow and celebrate the creative spirit of science will find itself also productive of the other forms of creativity which make life worth living. The societies where the bursts of scientific energy occur...span the other arts too.' This quotation is from a lecture given last year by William Waldegrave¹; he went on to present a recipe, with which I strongly agree. We must reverse what he termed the 'Balkanisation of intellectual life – an affliction as acute in the humanities as in the sciences'. He recommended a broader education, interdisciplinary contacts in universities, and 'public understanding' programmes. However, current trends risk moving the other way – towards conditions *less* propitious for real innovative thinking, or for a more integrated culture.

The UK Government 1993 White Paper 'Realising our potential' rendered explicit the doctrine that science could be harnessed to wealth creation; and also to enhancing the quality of life. (Incidentally 'creating wealth' and 'enhancing the quality of life' are not really equivalent 'ends' that should be

equally extolled. The Newcastle philosopher Mary Midgley, who writes cogently on such issues, reminds us that much economic activity is valued as a means, direct or indirect, towards enhancing activities that we undertake for their own sake.)

Most of us would broadly assent to what the White Paper's principal authors meant. Indeed there are echoes right back to Bacon: 'the emolument of life... and the relief of man's estate'. Yet some things being argued in its name risk being unwittingly detrimental to these shared aims. Unduly *dirigiste* policies would quench real originality. Not only would this be bad for basic research in itself, but it could compromise the research universities, whose standards are crucial for the quality of expertise entering industry and the professions, as well as the flow of new ideas – precisely the activities that have (in retrospect) been their prime contribution to the economy. (My biomedical colleagues may be more sanguine because they have more options for supplementing governmental funds from other sources.)

Budgetary competition is obviously acute – between science and other public spending, and among the sciences themselves – but efforts to make research more accountable and impose a business based perception of efficiency could backfire, for three reasons. First, assessment exercises, grant reviews, and so on can become so time consuming that they seriously erode effort. Second, the most original lines of inquiry cannot always be 'packaged' into acceptable research proposals. Third (and more insidiously) the most creative and astute individuals may be discouraged from pursuing a research career altogether. It is a poor deal if top quality innovative output falls by a bigger percentage than the financial 'saving'. We need to be businesslike. So does a hospital – so does even a church – but that does not mean that we should operate too like a business.

Despite Britain's poor showing in other international league tables, we certainly do not lag Germany and Japan in the quality and range of our discoveries. Nor do we lag economically in industries like pharmaceuticals, where the research emphasis is strong. The challenge is to remedy our relative weakness

in other sectors without jeopardising what is already doing well. Scientists can be excused for thinking that the problem lies not primarily in themselves, but in the low research and development investment in some sectors, and companies that are not even receptive customers for research or enlightened employers of scientists.

Because the universities and research councils are public bodies, the government has been able to enhance the industrial influence on them. What is lacking is enough diffusion the other way. Perhaps we need to match Germany and Japan in the number of scientists and technologists on company boards.

An international opportunity

It is not only in Britain that mechanisms introduced to make research more efficient risk backfiring. A survey by the physicist Leon Lederman, when he was AAAS President, revealed how young US scientists perceived their prospects and pressures as being worse than their predecessors'.

Despite its alleged malaise, US science maintains great vitality. This is because its catchment area for talent extends worldwide. The USA is a magnet for the strongest graduate students and researchers. These come especially from Asia, but from Europe as well. (After the collapse of the Soviet Union, many leading Russian scientists moved directly to the USA.)

Why should we not try to match the blandishments of the USA for internationally mobile talent? All too often, one hears of people being 'lured abroad', as though this drain is something we must resignedly accept. Yet, this country has impressive advantages through the quality and tradition of our best research institutions, and we have an unmerited headstart over our European neighbours through the primacy of the English language.

UK universities have a fine record for attracting overseas students, but we should surely press it further. Why not aim to be the country of choice not only for undergraduates, but for top ranking graduates, and for the potential leaders of the international research community – those whose first instinct is now to go the USA? Everyone is aware of

the benefits of the right kind of inward investment. Britain could surely exploit more fully its manifest comparative advantage as a magnet for talent, a location for research centres, and an incubator for discovery and invention. The law of increasing returns surely applies: an extra 5% funding would yield much more than a 5% boost. Conspicuous success feeds on itself by stimulating and drawing in more expertise. As one of the 'societies where bursts of scientific energy occur' – to quote William Waldegrave's words again – we would gain all the correlated benefits that he identified.

Young people: the 16–18 curriculum

This leads to the worrying issue of school education, where our international rankings are low. My remarks above on 'public understanding' omitted one specially crucial segment of the 'public': those still in school. The British Association runs programmes, all through the year, to build on young people's natural enthusiasm for science and technology. It is keen to foster and cooperate with innovative schemes that bring individual research scientists in contact with schools. There is growing scope here: telecommunications allow remote access to large facilities, so that individuals – amateurs at home, as well as young people in schools – can participate in scientific discovery. Future scientists may be less corralled into large laboratories.

Sir Claus Moser's Presidential Address in 1990 led to the National Commission on Education, run under the association's auspices and funded by the Hamlyn Foundation. There have been moves towards implementing a few of the commission's recommendations – on nursery education, and on coordinating vocational qualification – but there has been little movement on most others. Sir Ron Dearing is now reviewing the system of qualifications at 16 and 18; we hope he will interpret his remit broadly, and note the commission's strong emphasis on broadening the A level curriculum.

Young people opting for humanities should not drop all science when they are 16. An appreciation of science is vital not just for tomorrow's scientists

and engineers, but for everyone who will live and work in a world underpinned by technology – and even more vulnerable to its failures and misapplications than the present one. Even more important, the option of higher education in science and technology should not be foreclosed to them. (These concerns pertain to England more than Scotland. Scottish education has its admirers here, but few in Scotland advocate a switch to the English system?)

It is crucial that enough of the brightest young people go on to acquire some professional expertise in science and technology. They will not do so unless, when making the key decisions at age 16 or 18, they perceive a range of appealing opportunities. They will be discouraged if the courses do not inspire them; or if the exciting discoveries reported in the media all seem made in the USA (or, worse still, by people from this country who have defected overseas). They will be discouraged if scientists seem valued less than accountants; and they need to feel that science is humanly relevant – that it meets their ethical concerns.

The OST and the DTI

A word now on the recent reorganisation of government science in Britain. The science, engineering, and technology community broadly welcomed the setting up of the Office of Science and Technology (OST) in the Cabinet Office. William Waldegrave, as its first minister, gained wide respect for his genuine commitment. We in the British Association especially appreciate the OST's continuing support for our mission of enhancing public understanding of science.

The shift into the Department of Trade and Industry (DTI) surprised most of us. It seemed to reverse one of the few government initiatives of recent years that commanded genuine bipartisan support. There had been no overt pressure for the move, certainly no open discussion. Some industrialists (Sir Richard Sykes among them) have argued that from their perspective, and that of smaller companies, the change could offer benefits. We hope the move indeed proves beneficial, but it would be remiss not to mention the worries

some association members have, in the hope that they will prove groundless.

There is concern that there should not be an undue focus on research with a short term payoff – this is not just because we value curiosity driven research for its own sake (though we do), but because past experience suggests that it is through free ranging basic research that the universities can make their most distinctive contribution to boosting industry and meeting other public demands.

There is also concern that its embedding within DTI should not hamper the OST's efforts at deploying the overall case for science, and coordinating policy across other departments. Strong links are indeed needed with industry, but it is also important to strengthen those with defence, health, environment, and (perhaps above all) with education. And the new Chief Scientific Adviser must have a real cross-departmental influence – Professor May, an old friend of the British Association, carries with him our good wishes and confident hopes. Also the Commons Select Committee should continue – it is an index of parliamentary interest in scientific and technical matters.

Science is not a monolithic profession; not a single constituency; certainly not a lobby. It is a pervasive activity. As with other long term issues (energy and environment, for instance), it is best if national science policy is bipartisan, rather than the subject of strident debate. However, the 'downside' is that science then loses visibility on the political agenda. The British Association, with its broad involvement, and its traditions as an informal 'parliament of science', is well placed to extend its role as a policy forum; I think it has a responsibility to do so. Let us hope that long term issues will generally loom larger as the millennium approaches.

The atomic scientists

I should like to devote a few final comments to broader (even global) issues of scientific concern. We have recently marked the anniversary of the atomic bomb – an invention as 'different in kind' from anything before as gunpowder seemed to Bacon.

Many physicists who had worked at Los Alamos during the war returned to

academic work straight afterwards. Some of them founded the *Bulletin of Atomic Scientists*, a journal with the aim of alerting the world to the dangers of an arms race, and the urgency of arms control. The cover page of each issue shows a clock, the closeness of whose hands to midnight indicates how precarious the world situation is (or is thought to be by the journal's Editorial Board).

At the time of the Cuba crisis, the clock was at only 3 or 4 minutes to midnight. It was there again in the mid 1980s. At that time, the main issues were how to reduce the ever present risk of escalation towards catastrophic nuclear war – by malfunction or miscalculation, even if not by premeditated strategy. The risk in a single year may have been small, but the probability would have mounted up if conditions had not changed.

The nuclear arms race, from the 1950s to the 1980s, was fuelled not only by misdirected resources, but by misdirected inventiveness. Virtually every innovation was quickly matched by the other side, and the arsenals ratcheted upwards. Yet throughout this time some scientists (the founders of the *Bulletin* being among them) were using their international influence to foster arms control. In particular, there was constructive dialogue at the 'Pugwash' conferences, named after the village in Nova Scotia where the first meeting was held. The physicists involved in such conferences were in numerical terms trivial compared with those in weapons laboratories, but they constituted an informal channel back to their governments, and were genuinely influential in instigating formal contacts – especially in the 1960s, before other East-West channels opened up.

Scientific input into policy: the transatlantic contrast

From the 1970s, scientists from a younger (post-war) generation became active in arms control debates; some of these went on to hold official posts, either in the USA or in Russia. However, such people have no real counterparts in the UK, where we still rely on independent voices from the Second World War generation, who have maintained their concern ever since.

The reasons for this transatlantic contrast are not hard to find. In the USA, there is a 'revolving door' between government jobs and universities. (or organisations like the Brookings Institute) whenever the administration changes. The American Physical Society, the Union of Concerned Scientists, and other organisations, can draw on this independent expertise to prepare (often influential) reports. There is also the Jason Group – physicists of the highest academic repute who meet regularly, for several weeks per year, bringing fresh minds to bear on issues relevant to the Defense Department. Jason Group reports are generally classified, but its members acquire a background and credibility that enhances their effectiveness in open discussion.

Over here, on the other hand, government science is generally a lifetime career. The more pervasive secrecy inhibits well informed open debate. Defence scientists form a rather closed world. My own experience illustrates this. I have had contact with many physicists from Los Alamos and Livermore (who attend academic conferences, and contribute to the open literature), but not with their British counterparts. Greater openness could actually strengthen the defence establishments themselves. Their primary activities will (one hopes) be throttled down, but they must be helped to retain wide competence; arms control and verification will demand innovative ideas in many fields (chemical and biological, as well as physics based areas like space technology).

These specific points about defence science are a symptom of something that is routinely deplored at British Association meetings – the meagre input of scientists into the general political process in this country. This precludes informed debate on technical issues where well thought out new ideas are needed – energy, environment, and transport policy, as well as defence. We could learn from US practice and set up 'Jason style' groups – leading scientists from academe or industry who would not merely sit on advisory committees, but commit themselves to carry out serious interdisciplinary studies. This is something the new Chief Scientific Adviser might consider; or else an independent foundation.

Another valuable innovation would be a forum or institution that could fulfil, in the scientific and technical arena, the role that Chatham House fulfils in foreign policy. This is something that the British Association itself, perhaps with partner organisations, could seek to implement.

Global risks

The clock on the *Bulletin's* cover has been put back to 17 minutes to midnight. In nuclear terms, the world seems on a longer fuse, but bewildering new risks now confront us. These may not threaten a sudden worldwide catastrophe – the doomsday clock is now a less good metaphor – but are, in aggregate, as worrying and challenging.

The nuclear arsenals must be safeguarded, and gradually dismantled. Nor must new weapons proliferate, of types that require only minor adaptations of legitimate technologies that every nation aspires to.

For most of the world's people, the ideological stances of East and West were always an irrelevant distraction from the immediate problems of poverty, and natural hazard. These 'threats without enemies' relate to global questions of environment, resources, and biodiversity: how can these be safeguarded without jeopardising the aspirations of the poorer nations? There is no case for a brake on technical advances – the need, rather, is to accelerate but redirect them.

The thrust of economic development must, urgently, shift towards a mode that is more equitable, environmentally benign, and sustainable. This was a theme of Dr Anne McLaren's Presidential Lecture last year. She reminded us that education (especially for women) is a priority worldwide, not only for its own sake but because of its impact on family size. Stemming population growth may be a prerequisite for attaining acceptable quality of life everywhere.

I should like to quote related sentiments from a different quarter, the Prince of Wales. In a lecture at Cambridge University, he said:

The strategic threats posed by global environment and development problems are

GENERALIA

the most complex, interwoven, and potentially devastating of all the challenges to our security... Scientists... do not fully understand the consequences of our many faceted assault on the interwoven fabric of atmosphere, water, land, and life in all its biological diversity. Things could turn out to be worse than the current scientific best guess. In military affairs, policy has long been based on the dictum that we should be prepared for the worst case. Why should it be so different when the security is that of the planet and our long term future?

When the risks are global, the obligation to inform and to seek solutions extends to the international scientific community. Current concerns are much more diverse than those of the Cold War era, and cannot be tackled without wider expertise. Scientists in this country might have been reluctant to dedi-

cate their energies to *nuclear* arms control issues – in the ‘superpower’ confrontation, nothing Britain said seemed to count for much – but now that the agenda has changed, there need be no such inhibition. Britain has impressive credentials and a high international profile in the broad range of expertise that these global problems entail – problems that should loom as large in the political agenda as did the East-West political divide in the Cold War era.

Conclusion

I shall close with another brief cosmic perspective. Planets like ours – ‘cycling on’, in Darwin’s words, ‘according to the fixed law of gravity’ – are surely very common in the universe. But those

that harbour such *complexity* as ours could be surpassingly rare. The intricate biosphere, of which we are part, has taken several billion years to evolve, but in terms of cosmic timespans, we are not yet at the halfway stage – we could still be nearer to Darwin’s ‘simple beginning’ than to the endpoint of the evolutionary process.

It is, primarily, collective human actions that will determine how, or even if, that process unfolds. Being mindful of these potentialities stretches our horizons: it should deepen our commitment to understand our world, and conserve its web of life.

CONTACT PROGRAM ON INTERFACES OF CHEMISTRY AND BIOLOGY for M Sc students

Date: 28 October to 8 November, 1996

Place: Mumbai

This program aims to provide an opportunity to final year students of M Sc (Chemistry, Biochemistry, Biotechnology and related areas) or B Tech (Chemical Engineering and related areas) to get to know some of the frontier topics of research interest at the interface of Chemistry and Biology and to interact with some leading scientists in an informal atmosphere. The program will attempt to give a flavour of topics such as Structure of biomolecules, Biophysical methods, Enzyme mechanisms, Enzyme inhibitors and drug design, Enzyme models, Lipids and biological membranes, Nucleic acids and molecular biology, and Molecular electronics. Lectures on relevant topics will be given by leading researchers and the students will be encouraged to take part in the scientific discussions. The participants will visit various well-equipped laboratories to introduce them to some of the latest techniques. They will also be involved in experimentation, familiarizing and learning advanced computational and instrumental methods of analysis.

Essentials of Nuclear Chemistry. H. J. Arnikar, Fourth edition. Wiley Eastern Limited, 4835/24, Ansari Road, Daryaganj, New Delhi 110 002. 498 pp. Price: Rs 155.

The book presents a wide spectrum of topics, and some kind of comprehensive coverage on some of these, in the broad areas of nuclear-, radiation-, and radio-chemistry. It attempts to reach far beyond the 'essentials' of nuclear chemistry. The text is so much marred with typographical errors, conceptually wrong statements, grammatical errors and mis-information, that a student would be better off if he is not lured into reading this book, attracted by its charming appearance and get-up.

The author very often shows a lack of concern about the reliability and correctness of the data that are drawn from various sources. On page 7 (footnote) the half-life of proton decay is quoted from a 1981 unpublished work. This was OK for the first edition of the book published in 1982. But in 1995 the picture is very different. On page 403 (footnote) the ^{14}C specific activity in modern wood is quoted to be 13.6 dpm/g and to be controversial from a reference that is given in a text book of nuclear physics published in 1979. This issue must have been resolved by now. Taking another example, the oldest terrestrial rocks are stated to be 2.7×10^9 y, and the age of the earth is given as $(5.0 \pm 0.50) \times 10^9$ y, (p. 407), both values from a 1954 text. Even in 1981, these values had become obsolete. Much progress has been made in this field.

Examples of conceptually erroneous presentations:

(i) Page 4, line 3 from bottom: 'An atomic nucleus, considered without relationship to the outer sphere, is often referred to as a *nuclide*....'

(ii) Page 5, Section 1.3.1 (b) '*Isobars*: These are nuclei of different neighbouring chemical elements having....'

(iii) Page 8, line 11: 'This suggests.... the charge independent nature of the nucleons in respect of stability'.

(iv) Page 23: In Figure 2.1 the ordinate should be ρ/ρ_0 . (not ρ , as given) and the number 4.40 should be replaced by 4.4α .

(v) Page 23, Figure 2.2: The ordinate label 'Nucleon Density (Relative)' should be changed to 'Nucleon Density; 10^{44} nucleons/ m^3 '. The ordinate scale should have values from 0 to 2.00.

(vi) Page 25, eq 2.7b. It is incorrect to say that in this equation a , and b are constants.

(vii) Page 40, Section 2.92: 'If all the energy levels in an assembly of molecules.... were equally populated, no resultant magnetization would occur on the application of an external field.'

(viii) Page 41, line 3: 'In 1.8 g of water the numbers (of molecules) in the lower and higher energy states will be of the orders of 10^{23} and 10^{18} respectively'.

(ix) Page 54, para (b), line 4: 'Generally, a single crystal of sodium nitroprusside.... is adopted as a standard...'

(x) Page 56, para (c), line 2: 'However, when the environment is asymmetrical a feeble internal electric field operates and this leads to a quadrupole splitting of the line....'

(xi) Page 58, para (g) line 3: '...(The Curie point)... is also the temperature below which the single Mossbauer line splits into six lines due to a sharp decrease in the electron density at the nucleus.'

(xii) Page 83, Figure 3.3(b): The meaning and usefulness of $V_c(r)$ as shown in the figure, is not found anywhere in the text.

(xiii) Page 134, last line: An incorrect expression, $e^{\lambda_1 - \lambda_2}$, has been used. The exponent must be dimensionless. This mistake also occurs in the first edition of the same book by the author.

(xiv) Page 243, line 4 from bottom: '... the yield of symmetrical fission... is the lowest...'. This is not so.

(xv) Page 246, para 6.5 line 4: '... fission fragments.... fly apart with velocities much in excess of those of their orbital electrons.'

(xvi) Page 294, second sentence: 'Excepting γ which is purely an electromagnetic radiation, and neutrons which are uncharged, all other forms of radioactive samples emit charged particles as β^\pm , p, d, t, α ,... whose detection ...'.

(xvii) Page 182, Problem 4.1: '...1 g of ^{226}Ra emits ... atoms of radon' Using similar words can we say that ' ^{14}C decays by emission of nitrogen?'

(xviii) page 364 Section (b): '.... ^{14}C are formed continually in nature by an alternative interaction of fast neutrons of cosmic origin with the atmospheric nitrogen.'

(xix) Page 383, Equation 10.22: Using this equation and the data that are given, b comes out to be 0.88×10^{-16} and not 4.11×10^{-16} .

(xx) Page 430, Equation 11.3: The equation $\text{LET} \propto Mz^2/E$ is interpreted by the author as 'The above expression shows that LET increases upto a maximum as v decreases along the path, after which the LET decreases along with v .'

(xxi) pp 405–407, Section (c); Age of Minerals and Rocks: The matter presented in this section is erroneous on almost every point. The relation.

$$M = N_1(e^{\lambda_1 t} - 1) + N_2(e^{\lambda_2 t} - 1) \dots 10.38$$

has been simplified by the author to: $M = (N_1\lambda_1 + N_2\lambda_2)t$, and is used, on pages 406 and 407, to calculate the age of granites and the age of earth's crust using ^{40}K as a chronometer, whose half-life is 1.28 Gy. Since, for the values of ages involved, the exponent in eq. 10.38 is greater than 1, the adopted simplification is invalid. The author fails to note this, and using the invalid but simple expression, calculates the ages of granites, and that of the earth's crust respectively, as 10.1 and 8.6 Gy. He tries to cover the discrepancy by 'suggesting an overestimation of radiogenic calcium content'. He 'explains' the high K–Ar age by stating that 'the bulk of the present day Ar in the atmosphere was released thereto while the surface of the earth was still in the fluid form'. Such a scenario would, however, give a lower radiogenic argon and would go in opposite direction. The author, irrelevently, brings in the name of Professor Urey here – blatant misinformation.

(xxii) Pages 232–236, Section 5.12; The origin and evolution of elements.

This section is entirely incorrect and full of misconception. Ideas that have been found to be untenable are presented as valid explanations, while some of the well-accepted processes are presented with such distortions that they lose their meaning. We know that nucleosynthesis of elements beyond helium is not possible in Big Bang. The suggestion, presented in Section 5.12.3, that the medium weight elements were

BOOK REVIEWS

formed by fission of heavy elements fails to account for the presence of the p-process nuclides and has never been taken seriously.

Examples of some sentences that suffer from 'language problem':

(i) Page 79, para (f): 'The energy discontinuity is around 2 MeV, i.e. about 25% of mean binding energy in β disintegrations in the neighbourhood of magic numbers.'

(ii) Page 269, second para, last sentence: 'Since then ever so many reactors have been functioning in many countries at very many times higher power levels, extending upto 10^9 W.'

(iii) Page 227, first para, second sentence: 'This is in spite of its advantages in respect of the raw materials needed being very much cheaper and the process involving far less of radiation hazard as none of the by-products is radioactive which is not wholly contained.'

(iv) Page 290, third para: 'Let us note that reactor or no reactor, mankind has been exposed from the beginning of time to nuclear radiations of cosmic and terrestrial origin, besides those due to ^{40}K present in all rocks and the seas and in our very body, besides ^{14}C .'

Wheat Revolution – A Dialogue. M. S. Swaminathan (ed.). Macmillan India Ltd., P.B. No. 7092, Daryaganj, New Delhi 110 002. 1993. 164 pp. Price: Rs 224.

This book contains the history of growth of wheat production in India, leading the country not only to self-sufficiency but to food security. Revolutions are a radical change in the constitution of a country after revolt, which are often violent, and after a change in government dissipate over time. 'Wheat revolution', however, saved the country from going through a revolution as was predicted by some writers from developed countries. Has the 'Wheat revolution' dissipated as pointed out by Mr.

Shivaraman? Therefore, recapitulations of events, in the form of a dialogue by major actors which led to 'Wheat revolution' synonymous with green revolution was an appropriate and laudable effort. M. S. Swaminathan, who organized the dialogue at M. S. Swaminathan Foundation, and had the central role in it, is to be commended for bringing out this book for the benefit of present and future generations.

Several questions have been raised in the recent past about 'Wheat revolution/Green revolution' relating to leadership, scientific basis and policy actions. The book provides answers, to some extent, to these questions through group discussion on (a) Package of technology, including new varieties, agronomic practices and post harvest handling, (b) Package of services, including the timely supply of seeds, fertilizer, water and credit and (c) Package of public policies, assured and remunerative marketing, building of grain reserves, etc.

It is obvious from the discussions that till 1963 there was no technology when the seeds of varieties having Norin dwarf traits in spring wheat background were obtained in sufficient quality from Borlaug to plant experiments at IARI (Indian Agricultural Research Institute, New Delhi). Since this material was found promising at Delhi, Ludhiana and Pantnagar, a decision was taken to put demonstrations in farmers fields, thus by-passing the usual norms of coordinated trials and extension programmes. This speaks of the confidence of scientists in adopting an alternate strategy. A large amount of credit goes to decision makers, particularly C. Subramaniam who agreed for the import of 18000 tonnes of wheat seed from Mexico of the varieties which were already identified at Delhi, Ludhiana and Pantnagar. This material was planted in Punjab (then Punjab and Haryana) and Western UP where the climate was suitable for wheat production and supported by assured water supply, and enterprising farmers. Within three years production jumped from 12 to 17 million tonnes from 1965 to 1968. There would have not been so much success if the decision to purchase red wheat by government at the same price as desi wheat was not taken because the red grain of new varieties did not fetch good price in

open market. Even today the amber varieties derived from Mexican dwarfs such as Kalyansona, HD2329, HD2285 and others fetch less price than desi varieties such as C306, NP824, K68 and others. Thus the purchase price was an important decision for encouraging wheat production. Having got success with production, it was necessary to develop varieties with amber grain colour as against the red colour and chapati quality acceptable to consumer. Interestingly, a population S227 which came from Mexico provided several amber grain selections such as S227, S307, and S308. The selection S227 was named as Kalyansona which had performed very well at Delhi, Ludhiana and Pantnagar. Kalyansona was an acceptable variety for grain colour but still required improvement for chapati quality. Later on several crosses using Indian varieties and new dwarf varieties were made and varieties with better quality were developed. The technology with reference to irrigation and fertilizer application was developed. It so happened that 1964 and 1965 had deficient monsoon rains, and possibly a kharif crop preceded wheat crop, therefore, six irrigations appeared to produce the maximum yield. At that time not much attention was paid to soil-moisture profile and winter rains. However, the recommendation of five to six irrigations was extensively popularized and made sacrosanct. This led to over-irrigation and with considerable difficulty, now, the reduced number of irrigations are an acceptable recommendation. It also took time to fix an economic dose of fertilizers which is dependent on location, variety, irrigation, etc. The most fortunate aspect of wheat production in India is that we have no insect pest problem and the Indian scientists from the time of K. C. Mehta and B. P. Pal have been experts in breeding for rust resistance.

The 'package of services' includes the recommended seed for a given location, irrigation, fertilizer availability, and any other input such as machinery or energy which now have become important. In the initial phase 1966 to 1968, the target area was Punjab (Punjab and Haryana) and West UP where most of these services were available. However, there was a coordinated effort among scientists, bureaucrats, politicians and above all

the farmers. The need of the hour was to increase production and hence everyone made his or her contribution to this national goal. The 'dialogue' brings out clearly that the scientific awareness, vision and intuitions of M. S. Swaminathan, combined with clarity and commitment to national objectives of C. Subramaniam were the major contributors to 'wheat revolution'. The late B. P. Pal gave all the encouragement to scientists and the late V. S. Mathur bred a number of varieties which even today

are the dominant varieties. The country owes them gratitude for their accomplishments. There was, however, a significant role of the Indian Agricultural Research Institute, New Delhi, Punjab Agricultural University, Ludhiana and G. B. Pant University of Agricultural Sciences & Technology, and their scientists who worked together to make a success of dwarf wheats in India. Norman Borlaug through his material and visits to encourage scientists played a pivotal role in this programme.

There are some activists in the country who have been critical for wheat/green revolution for various reasons. They are entitled to do so because they have enough food available to them and have rarely experienced the scarcity of food.

COSTED-JNCASR Fellowship Programme

This Fellowship Programme has been jointly instituted by the Committee on Science and Technology in Developing Countries (COSTED) and the Jawaharlal Nehru Centre for Advanced Scientific Research (JNCASR) to foster free mobility and exchange of scientists in developing countries and to promote South-South co-operation. The JNCASR, operating under the direction of Prof. C. N. R. Rao, FRS, is a centre of excellence in Bangalore, India and essentially works through close links with several reputed academic scientific institutions and centres in India.

The fellowship covers short-term research, training or participatory research work in physical, chemical and biological sciences in reputed scientific institutions in India including the JNCASR. The programme is open to scientists, teachers and research scholars in the developing countries in the Asian, African, Arab and Latin American regions (except India).

The duration of the fellowship is up to 3 months. The fellowship covers free lodging as well as an adequate allowance in Indian currency to cover boarding. A few travel grants are available for exceptionally meritorious candidates.

The applicant must be a scientist, a teacher or a research scholar affiliated to a scientific or academic institution and below 45 years of age. For further information on the programme, contact:

Third SERC School on Seismology and Earthquake Processes

Date: 23 September – 12 October 1996
Place: Dhanbad

Theme: Computational seismology and induced seismicity. The course content includes: Fundamentals of seismic wave propagation, Seismometry and accelerometry, Observational seismology, Focal mechanism of earthquakes, Seismicity and seismic zoning, Fractal analysis of earthquakes, Digital seismograph and telemetry, Signal processing, Data analysis—digital and statistical, Reservoir-induced seismicity, Mining-induced seismicity, Special lectures on topical themes.

INTER-UNIVERSITY CENTRE FOR ASTRONOMY AND ASTROPHYSICS

An Autonomous Institution of the University Grants Commission

IUCAA requires a Software Engineer (Scientific/Technical Officer 'C' having qualification and experience given below for developing software to interface the instruments with computers working with different operating systems (DOS, LINUX, UNIX, etc)).

Scale of Pay: Rs 3000-100-3500-125-4500 **Age limit:** 35 years (Relaxable by 5 years for SC/ST)

Qualifications: BE or M Sc (Electronics/Instrumentation/Physics.)

Experience: 5 years experience in software/hardware instruments.

Higher start may be offered depending upon qualification and experience.

Interested persons should send their application in the following format:

1. Full name
2. Address for correspondence
3. Permanent address
4. Nationality
5. Date of birth
6. Whether belonging to SC/ST, give details and attach caste/tribe certificate from the competent authority
7. Names and addresses of two referees
8. Educational qualifications with complete details:

Name of Institution/Board	Year of passing	Exam/Degree	Main subjects	Marks % in aggregate and division
---------------------------	-----------------	-------------	---------------	-----------------------------------

9. Experience, with complete details:

Name and Address of Employer/Instt.	Period of service From-To No. of yrs. and months	Post held, pay and scale of pay	Whether permanent or temporary	Reasons for leaving
-------------------------------------	--	---------------------------------	--------------------------------	---------------------

10. Any other relevant information.

Applications must reach **within 15 days** from the date of this advertisement addressed to:

The Senior Administrative Officer,
IUCAA, Post Bag 4, Ganeshkhind, Pune 411 007.

INTER-UNIVERSITY CENTRE FOR ASTRONOMY AND ASTROPHYSICS

An Autonomous Institution of the University Grants Commission, India.

The Inter-University Centre for Astronomy and Astrophysics is setting up an optical near-infrared observational facility with a 1.5-2 m size telescope. In order to carry out development of various instruments for the observations, the Instrumentation Laboratory of the Centre is looking for a YOUNG PHYSICIST, for the position of Scientist C, with a Ph D in any branch of experimental physics and having an aptitude for instrumentation. The selected candidate would be placed in the scale 3000-100-3500-125-4500, with the usual allowances applicable to central government employees stationed at Pune.

Further, as the Giant Metrewave Radio Telescope of the National Centre for Radio Astrophysics is nearing completion, IUCAA is also looking for a YOUNG RADIO ASTRONOMER in the same grade with a Ph D in radio astronomy, to help initiate any joint projects with the NCRA.

Please apply to the Director, IUCAA, P. B. No. 4, Ganeshkhind, Pune 411 007, with biodata and a list of at least three referees. The applicants should ask these referees to send their confidential recommendations directly to the Director.

Using Agricultural Diversity Research Award

The Award

The Using Agricultural Diversity Award assists groups and institutions in India, Nepal and Bangladesh to undertake applied research on the use of agricultural diversity to meet farmer needs. The award is intended to encourage research collaboration, exchanges and dissemination of information on practical means to widen the range of crop varietal choices available to farmers.

Eligible Fields of Study

Applications will be accepted for applied research on topics related to:

- Testing and developing participatory approaches and methods for enhancing the on-farm use of agricultural diversity.
- Collaboration among groups currently engaged in on-farm conservation and enhancement of agricultural diversity.
- Informing policy of the role of farmer participation in on-farm conservation and enhancement of agricultural diversity.

Program Areas

Awards will be given in three Program Areas. Applicants must indicate the program area for which they wish to be considered, and may not apply to more than two program areas in the same cycle of competition.

Research Program

The Award will be used to support activities that seek to:

- Improve the practice and extend awareness of participatory crop selection and breeding efforts/or,
- Enhance the dynamic nature of community level seedbanking and seed supply initiatives by increasing the range of crop varieties available to farmers so as to meet changing needs/or,
- Explore links between community seedbanks and national or regional genebanks in order to improve seed security/or.

Exchange Program

The Award will be used to facilitate systematic exchanges among groups in South Asia engaged in or concerned with the conservation and enhancement of agricultural diversity on farm. This could include field visits by individuals to project sites, joint diagnostic and monitoring exercises involving more than one institution, consultation with specialists regarding methodological issues or the design and development of collaborative research projects.

Documentation and Dissemination Program

The Award will be used to undertake activities which contribute to the documentation of particular experiences with using agricultural diversity on farm and for disseminating the results of institutional activities, with a special emphasis on informing policy of participatory approaches and methods involving the conservation and enhancement of on-farm

agricultural diversity. Preference will be given to dissemination activities that make use of the internet and other forms of electronic mass-communication.

Eligibility

Applicants must meet the following conditions for eligibility:

- Research is in one of the eligible fields of study;
- Provide evidence of affiliation with an institution or organization in the region in which the applied research will take place;
- Provide evidence of previous work in the field of agricultural diversity conservation and use.

The award is principally to cover applied research costs; it cannot be used for permanent salaries or for the purchase of vehicles and other major fixed assets.

Duration of Tenure

Award tenure corresponds to the period of proposed activities. In general, this will be not more than 24 months.

Value

The Award will cover justifiable applied research expenses to a maximum of Rs 350,000.

Deadlines

There are two cycles of competition. All supporting documentation must be complete before the application will be considered. The deadlines for receipt of applications for each cycle are:

October 1, 1996 (awards will be announced mid-January)

February 1, 1997 (awards will be announced mid-April)

Applications

The Award is governed by a Steering Committee comprised of individuals from a wide range of national, regional and grassroots organizations in India, Nepal and Bangladesh as well as representatives from donor agencies.

Applications should be sent to:

Prof. S. K. Sinha

Chair, Steering Committee

c/o International Development Research Centre (IDRC)

17 Jor Bagh

New Delhi, 110 003, India

Fax: 91-11-4622707

email: UDRA@idrc.ca

This award is supported financially by the International Research Development Centre (Canada) and the Overseas Development Agency (United Kingdom)

Application Form
Using Agricultural Diversity Research Award

Name and Address:

Please submit all documents listed below. All documents must be received before applications are considered.

1. Summary of Research proposal (approximately 10 pages, not inclusive of bibliography) including:
 - project title and program area for which you wish to be considered
 - brief description of agricultural biodiversity in the region where the research is to be undertaken
 - explanation of how farmers perceive the use of agricultural biodiversity in their system of agriculture
 - research objectives
 - methodology
 - tentative schedule of field activities
 - ethical considerations
 - expected results and proposed monitoring mechanisms
 - potential use of results
 - possible beneficiaries of the research
2. Budget for proposed research
3. Application form (this page)
4. Curriculum vitae of principal investigator and co-investigator (if any)
5. Two references who will act as advisors (with full addresses)
6. Letter from institution confirming affiliation
7. Proof of citizenship or permanent residency

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted. Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally

not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21×28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The title should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355-362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319-322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

We'll help you get there

If you're selling science books/journals or laboratory products, or wish to recruit scientists in your establishment, then

**you're sure to benefit by
advertising here.**

Because *Current Science* reaches nearly every university, scientific institution and industrial R&D unit in India. What's more, it's read by hundreds of individual subscribers—students, doctoral scientists and professionals in virtually every field of scientific activity in India.

Current Science has the largest circulation among scientific journals in India.

And to give you more impact, we're now bigger, and better.

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted. Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally

not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21×28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355–362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A), Academic Press, New York, 1970, vol 1, pp. 319–322.

In this issue

How heavily does it rain in India?

Which place in India holds the record for the heaviest rainfall – Cherrapunji, Bombay or Mawsynram? Almost all of us will mark Cherrapunji as the correct answer. However, as described by P. R. Rakhecha and P. R. Pisharoty in their article on **page 179** of this issue, all the three places can legitimately vie for the first position.

One can talk of rainfall at various temporal scales – an hour, a few days, or the whole season; and interestingly, three different places qualify for the top slot in these three categories. Using the rich collection of the data at the India Meteorological Department, Rakhecha and Pisharoty have brought out some fascinating aspects of the heavy rains seen in the Indian monsoon season. Particularly intriguing are the depth–area–duration values associated with cyclonic storms. Even one look at a typical entry is enough to conjure up visions of a 100 km × 100 km area, completely covered to a depth of over half a meter of water in a matter of a couple of days.

Thunderstorms, responsible for heavy rains lasting for an hour or two, on the other hand, focus their attention on a much smaller area. Furthermore, thunderstorms of different intensities seem rather arbitrarily distributed across India. Who would have imagined the rainiest hour recorded in Hyderabad to be wetter than the one recorded in Kodaikanal or in Trivandrum or in Mahabaleswar? See **page 179** for more such surprises.

N. V. Joshi

Fighting the common cold

To sufferers of the common cold, the inability of the pharmaceutical industry to develop either a vaccine or an effi-

cient cure has always been a source of puzzlement. Grandmother's remedies and benign neglect are frequently the best course of action, although Pauling's followers still insist that vitamin C works wonders. Has modern biology contributed to understanding this widespread and most annoying affliction? On **page 193**, Michael Rossmann reviews the spectacular success of crystallography in delineating the structure and receptor interaction of a human rhinovirus, which belongs to a family of causative agents that are responsible for common colds. As far as biological organization is concerned, viruses are amongst the simplest organisms; however their atomic level structures are easily the most complex to have been determined by crystallography so far.

The rhinovirus structure reveals a 'deep crevice or canyon' on its surface which is the site for recognition by a cell surface viral receptor; permitting entry of the sub-viral particle or viral genome into the host cell. Here, the viral genes can be replicated, eventually leading to viral multiplication, resulting in a new generation of infectious particles. Rossmann's story is rich and detailed, providing insights into virus–receptor interactions. For the rhinovirus, the cellular receptor, which permits the infectious agent to home in, is the intercellular adhesion molecule-1 (ICAM-1), a complex membrane bound protein belonging to the immunoglobulin superfamily. The 'canyon hypothesis' for the receptor binding site on the virus immediately suggests possibilities for blocking the pocket and hence promises rational development of new anti-viral agents. Unfortunately, drug-resistant mutations can quickly develop, where the virus modifies the residues on the canyon walls and floor to preclude binding of potential therapeutics. The importance of the 'canyon' on the rhinovirus for receptor binding also rationalizes the inability of viral antibodies to efficiently inhibit virus–receptor interactions. The virus is cleverly able to hide the crucial bind-

ing site from immune surveillance. The battle against pathogenic organisms is clearly unending, with the enemy displaying formidable capacities for deviousness. In the case of the common cold, the advantage undoubtedly still rests with the rhinovirus.

P. Balaram

Microbe–drug wars

Drug resistance is a growing public health threat, with pathogenic organisms quickly learning to cope with the challenges posed by therapeutic agents. The strategies used by microorganisms include enzymatic degradation of the drug molecule, as in the case of penicillin resistance, where β -lactamases break down the antibiotic. Alternatively, clever microbes even alter the target structure as exemplified by vancomycin-resistant bacteria, which have modified cells walls containing lactic acid instead of alanine. This simple device eliminates a stabilizing hydrogen bond to the antibiotic, preventing its binding to cell wall precursors. A third stratagem involves membrane bound proteins which function as pumps and extrude the drug from the target cell. The problem of multidrug resistance in bacterial infections and cancer chemotherapy stems from the ability of the target cells to use the membrane bound pump as a 'hydrophobic vacuum cleaner' to sweep largely apolar organic drugs out of the cell. The understanding of multidrug resistance genes and their protein products has been growing, as reviewed by Rajendra Prasad *et al.* on **page 205**. Indiscriminate use of antibiotics and other therapeutics, compounds the drug resistance problem. The importance of developing new generation therapeutics cannot be over emphasized.

P. Balaram

**Indian Institute of Science
Bangalore 560 012**

Applications are invited from Indian nationals preferably below the age of 35 years, for faculty positions at the level of Assistant Professor in the Department of Electrical Engineering. The candidates, if selected, are expected to contribute effectively in the teaching and research programmes of Department which are generally in the areas of Power Systems, Power Electronics, Systems Science and Signal Processing.

The candidates should have a Ph D degree with three years of experience. The requirement of experience may be relaxed in the case of exceptional candidates. They should have an outstanding academic record and potential for independent research and leadership. Total emoluments is Rs 10,250 per month at the minimum of the scale of Rs 3700–5700. Interested applicants may send their curriculum vitae enclosing list of publications, names and addresses of three referees to the Chairman, Division of Electrical Sciences, Indian Institute of Science, Bangalore 560 012, India, on or before 15 September 1996. The referees may be requested to send their assessment directly to the Chairman, Division of Electrical Sciences.

For further details, please contact the Chairman, Electrical Engineering Department
at yvvele@vidyut.ee.iisc.ernet.in.

The candidates are welcome to refer to iisc home page URL <http://minchu.ee.iisc.ernet.in>.

R(IA)308–12/96

Dated 25 July 1996

REGISTRAR

**COUNCIL OF SCIENTIFIC AND INDUSTRIAL RESEARCH (CSIR)
NEW DELHI, INDIA**

ADVERTISEMENT NO. 10/96

POSITION: DIRECTOR, REGIONAL RESEARCH LABORATORY (RRL), TRIVANDRUM

CSIR, the premier agency established by the Govt of India to undertake scientific and industrial research in the country, is looking for suitable scientist/technologist for the post of Director for its Regional Research Laboratory (RRL), Trivandrum. RRL, Trivandrum is a multidisciplinary Laboratory and is devoted to R&D work for the optimum utilization of regional/national resources; to undertake research work in the areas of environment sciences and waste water treatment; to undertake advanced and futuristic research leading to generic technologies; to provide consultancy services to industries for upgradation of skill and productivity; and to help in the human resource development in the areas of S&T in collaboration with universities and allied research institutions in the region. The major R&D programmes of the Laboratory cover – search for bioactive/polymer compounds from natural resources and development of new synthetic systems of technological interests; agro-processing of and value addition to spices, coconut, oil palm, cassava, etc; development of technologies related clays and rare earths; market-driven research and technology development in the area of effluent treatment systems; development of analytical procedures for measurement of metal pollutants, etc. The Laboratory offers consultancy services to industry and government agencies in the areas of its expertise.

The post carries the pay scale of Rs 5900–200–7300 plus allowances as admissible to Council officials. The appointment to the post will be on contract for a period of six years or superannuation, whichever is earlier.

For further details, please contact the Director-General, CSIR, Rafi Marg, New Delhi 110 001, India, (Fax, 3710618; Telex; 031–65202 CSIR IN, 031–66147 CSIR IN; Gram, CONSEARCH, New Delhi).

Interested candidates may send their complete biodata by 30 September 1996 to the Director-General, CSIR, Rafi Marg, New Delhi 110 001.

CORRESPONDENCE

Merit and mockery

Most academic and scientific jobs in our country are available in government organizations. Over the years, the ratio of the number of job seekers to the number of available vacant positions in these sectors has increased many fold. However, given the importance of these sectors for developing human resources and strengthening scientific and industrial bases, meticulous recruitment of meritorious, innovative and efficient persons is essential. Unfortunately, in most cases, these criteria are overlooked.

Whenever vacancies arise for such positions, these organizations place formal advertisements in the leading newspapers stating, 'Applications are invited from Indian citizen for...' to fulfil the norms, rules and regulations set by Indian law in this regard. However, it is an open secret that in many cases more favoured candidates are already around to occupy the available position. Obviously, the other aspiring persons being unaware of the real position, also apply for the same post. The treatment of these job aspirants during the 'mock' interview is saddening.

All will undoubtedly agree that interviews are conducted to assess the merit of a person for the job, not to expose his ignorance. The technical skill, awareness, outlook, temperament and above all knowledge on the particular field should be tested. On the contrary, the (biased) interviewer ask questions that do not help to reveal merit but highlight the 'imperfections' of the candidate, just to keep him at bay.

Is it ethical just to pretend during interviews? Is it a healthy practice in the overall interest of the organization and, in turn, for the country to have farcical interviews? Do interviewers ever think how much mental agony the candidate has to undergo when treated unfairly during a job interview?

When too many persons chase a few jobs, the employer is privileged because of the opportunity to pick up the best of the aspiring candidate. However, this may be true for a job in private organizations and may not be applicable for government jobs, where there are a lot of 'pushes' and 'pulls'. But should the interviewer be neutral and judicious, they could safeguard the interests of meritorious candidates.

B. K. PADHI

*Department of Biochemistry,
Bose Institute,
Calcutta 700 054, India*

Biotechnology

The write up by A. S. Rao on 'Biotechnology; What's in a name' (*Curr. Sci.*, 1996, 70, 955) makes interesting reading. Today, every biologist in India wants to be called a biotechnologist and why not. After all, as the Hungarian scientist rightly said, even pig rearing is biotechnology.

It is true that all our biotechnology institutions from the top downwards, are managed by biologists or those who have tinkered with biology. Universities and national laboratories are racing with each other to start biotechnology departments not bothering to see if they can find correct persons to man these new units. Some industries have also jumped on the bandwagon and have started bottling old wine in the new bottles. This is not all. Universities have also introduced, special admission tests to mislead the young to think that biotechnology programmes are professional programmes. No doubt, some

new techniques such as cloning, PCR, ELISA, manipulation of cells and the genetic material have been developed for use by all biologists. Mere using these techniques does not make a biologist a biotechnologist.

In the sixties, it was the craze for molecular biology and today, it is biotechnology. Like all other things, this craze will also slowly subside. This is reflected by the decrease in the number of students who take the all-India admission tests for postgraduate programmes in biotechnology. Our national funding agencies, instead of bringing together biologists of all types together, have only helped in creation of closed pockets by liberally funding programmes that were already in existence. While in some advanced countries the new techniques have helped in improving old biological processes, despite substantial support for this new area since the past two decades, nothing worthwhile has come out. All that has happened is new name plates and boards have come up all over. Perhaps, things could have been different had our managers been trained biotechnologists!

P. TAURO

*Department of Microbiology,
College of Fisheries,
UAS, Mangalore 575 002, India*

We now probably have a very large number of molecular biologists besides biotechnologists. True discrimination between a technique and a discipline or branch of knowledge is lost now. A major thrust of biotechnology involves genetic manipulations to produce a new useful entity. How does a biochemist, a botanist

CORRESPONDENCE

or zoologist working with a few enzyme estimations call himself a molecular biologist/biotechnologist/molecular virologist competent to teach and research in biotechnology, molecular genetics, molecular biology, virology or whatever? These areas require skills in a host of techniques and an interdisciplinary background is a must, as evidenced only by high quality research publications in relevant areas. Unfortunately, masquerading is common, with little regard for actual quality work, real expertise, relevancy and students' development in a discipline.

Graduate and postgraduate syllabi are decades old, though the school and pre-

university syllabi have been improved, though not necessarily in terms of practical training. Teachers rarely care to update themselves qualitatively in all respects, resulting in the destruction of the graduate and postgraduate education system.

Is there a remedy? Yes, when the sensitive, educated professionals react at qualitative level all over the country, flood with letters the Central and State ministries, the Vice-Chancellors, Director/Director-General/Chairman/Secretary of Institutions, etc., for changes in the Acts of Universities to include accountability, relevancy and competency both in academics and administration.

We should now create urgently a watchdog agency for ensuring quality education, and to control scandals. Will such people get together in large numbers in different places and demand quality? Continuous consistent lobbying should give results rapidly. The sceptres of WTO and IPR should urge us into action.

OPINION

Global errors in science: Traps of chance and prejudice

K. N. Ganeshaiah

Despite the awareness that the chances of a given ticket holder winning a lottery are dismally poor and sufficiently low enough to inspire any buying, several lakhs of people buy lottery tickets every month and lottery has been surviving as a successful enterprise. Clearly the inspiration for the buyer does not come from those millions who have lost their rupees but from that occasional lucky winner who bags several lakhs of rupees. His smiling face printed in the magazines makes news and several more millions are induced to buying tickets; though they all are mostly bound to lose, again there is another lucky winner who helps maintain the buying chain and the lottery continues to survive. Thus unlike that of the proverbial chain, the strength of this lottery chain is reflected not in its weakest length (the million losers) but in the strongest link (the lucky winner).

Surprisingly, a similar process of occasional 'discovery' seems capable of sustaining a chain of false inventions in science on a global scale. Such a possibility has recently been pointed out by Bill Amos¹ from the University of Cambridge and discussed in the columns of *Nature*^{2,3}.

Assume that a certain interesting pattern (irrespective of how one wishes to define

it⁴) has been proposed by a research worker in a symposium and that 20 of the participants are inspired to test it after their return. Even if the pattern does not exist, the laws of probability ensure that purely by chance one out of these 20 would find evidence for the pattern ($p < 0.05$). He would obviously be prompted to publish it because of his faith in the statistical significance of his experimental results and also because they are supporting what has already been held by others. The remaining 19 who could not get the 'expected' results may either feel less confident of their experimental protocols or more frequently do not find it interesting enough to publish the non-significant results. Occasionally some of them who do attempt to publish might find it hard to convince the referees against a pattern that is probably already making news.

Now assume that the paper published by the lucky scientist who got the results 'right' is read by a thousand research workers world over and that they would attempt to repeat the experiments. Again by the rules of probability, 50 of them would find the pattern to be true (< 0.05) and among them 10 would find it very highly 'significant' ($p < 0.01$). Even if only 30 of these 50 publish their results,

it leads to a chain of the publications demonstrating a pattern that indeed does not exist!!

Chance and prejudice as traps

What happens next? Does this global chain of errors continue? Or would the self-correcting mechanism of science set it right? Certainly as a preliminary step, the scientific community is likely to celebrate this news and the scientists would begin working further on this pattern that has by now become 'established'. As I argued elsewhere⁴, 'every pattern shown or demonstrated has the same effect as a miracle would have on the spread of a religion or the religious belief'. Such an error where a pattern is 'found' while it does not exist is termed Type I error in science and has the likelihood of not being noticed because of two reasons: one, the prejudice and the other the trap of chance.

First, scientists generally suffer from a prejudice of looking for only significant results—a syndrome that has been perpetuated by their incessant obsession to find patterns⁴. Consequently they have an instinctive desire to search for the existence of patterns, such that any work that does not find the pattern gets less or no

attention both by the investigators and also by the rest of the scientific community. Therefore in situations where no pattern exists, 95% of the work demonstrating no pattern is likely to remain unpublished or if published might go unnoticed. This attitude of science is an important fitness component that has contributed for its survival⁴.

Second, the scientific acceptance and approval of the pattern is innate in the statistical grammar or code the science has adopted for its own conduct: the results of the investigators who find the pattern significant has to be 'accepted' though it is likely that these might be only those statistically lucky investigators. Only a global observer with a bird's eye view of all the investigators could find that 95% of the workers have not been able to observe the pattern and have not reported this fact. But since the evaluation of the facts is not a well-coordinated global activity, rather is based mostly on individual cases, the 95% of the investigators are not going to add to the establishment (de-establishment) of 'the fact'.

There is one objection however: statistically if 50 scientists find the results significant by chance, 25 of them shall find the pattern in a positive direction and 25 in the negative direction such that the publication of both of these would end the matter and settle for a lack of pattern. But as Robert West³ points out, scientists often seek trends in one direction (perhaps positive) and hence the chain process of reporting the results that 'conform' to the already held pattern would perpetuate.

Global errors as stochastic events

The operation of global errors of this nature is in fact a pure consequence of the stochastic events reinforced by a positive feedback process. Such process has been recently realized to be important in several fields⁵. It is consequent to the way in which the probability often drives a random system towards a pattern that appears deterministic.

Consider an industrialist planning to release two models of a new product to the market. Both the models have similar efficiency and hence he has no idea which of the two would make a breakthrough. Therefore he has formulated a simple strategy for further production of the

model that customers like most: to begin with he releases just one unit each of the models and every time a unit of a model is sold in any of the outlets, he shall produce two units of that model and distribute. This way the production is directly linked to the rate of sale and the producer also guards against the overproduction of the model that does not sell well.

Accordingly, when the first customer buys one of the two models (say A), the industrialist releases two units of that model. Similarly the information on the model bought by the next customer is fed back to the producer who in turn releases two more units of that model to different outlets.

As this process goes on, and once the selling counters are flooded with the product, what would be the likely proportions of the two models in the market? Note that the marketing started off with one unit each of the models and that they cannot be discriminated by the customers as they do not have any specific differences in their customer appeal features; in fact their 'selection' of, or preference for, a model is a random process and hence would be in proportion to their availability in the market. Obviously we find it reasonable to expect that the frequencies of the models remain equal.

Figure 1. Frequency of red balls after every draw in three simulations of the Polya-Urn model. Note that the frequency begins with 0.5 as there are one each of red and white balls and hence it is generally expected that the frequency fluctuates around this (horizontal line). But as the process (draws; iterations) starts there will be an initial wiggle in the frequency which eventually stabilizes at some final proportion (p) in the range from 0 to 1. Summary of 2000 such simulations is presented in Figure 2.

But the mathematicians have shown that under such situations it is most likely that the market stabilizes with one of the models dominating over the other! Further, were the whole process to be repeated in another isolated island the chances are that the other model dominates the island market! In other words there is no way of predicting the fate of such models in advance.

The underlying stochastic events are well known to the mathematicians as the Polya-Urn process. The phenomenon can be visualized with a huge urn (market here) containing a red and a white ball (the models here); a ball is randomly drawn and returned to the urn with an additional ball of the same colour (as the industrialist does with the sold model) and the process is repeated. If one keeps track of the frequency of the two colours, initially, when there are just a couple of balls in the urn, the proportion of any colour shows heavy wiggles (Figure 1) because even a slight random bias in picking a particular colour can cause huge changes in the proportion. A chance favoured bias in drawing only red balls for instance, adds more red balls to the urn and increases the probability of drawing red balls further. However as the number of balls in the urn increases, this proportion converges to some limiting value p and as the urn gets filled with a large number of balls, the system becomes resistant to any random bias in picking the balls and hence gets stabilized. What is most interesting is that p can take any value between 0 and 1 (Figure 1).

I have simulated this process 2000 times and the results are plotted in Figure 2: clearly all values of p are equally

Figure 2. Frequency of the final proportions (p) of red balls in 2000 simulations. Note that all levels of p are equally probable and hence it is very difficult to predict the fate in advance.

probable! In other words, back to the marketing scenario, the extent to which a particular model dominates is purely a consequence of the history of the market and not a deterministic process. That science might frequently use these deterministic end results as the basis of investigation and attempts to probe for deterministic causes is another issue. A far more serious consequence of such stochastic process is the possible feedback chain of erroneous reports it might start off in science. As described earlier, such stochastic events based on the permissi-

bility of the statistical codes of conduct adopted by the scientists might start a chain of false discoveries that might never appear to be the global errors in science. It appears it is very imperative to evaluate the extent to which our scientific information is clouded with such global errors generated purely by chance and nurtured by the prejudices of scientific community. As Bulstrode⁶ quips in *Nature*, 'The logical conclusion is, sir, your journal may be merely noise'.

COMMENTARY

A survey of Himalayan resources

David A. Spencer and Rasoul B. Sorkhabi

Himalayan geology is increasingly drawing the attention of the international geological community. In response to this 'global age of Himalayan geology', several community services and information networks have appeared in recent years. Recently, we conducted an international survey among Himalayan researchers to evaluate how they use these resources, and to find what improvements can be made to them. The survey was sent out in February 1996 to some 500 active Himalayan researchers in various countries, whose names were available to us. There was a truly international participation in this survey, reflecting the current range of researchers from many countries. The survey was also posted twice on the electronic mail network 'HimNet' (4 and 25 February 1996), which has a distribution to 580 researchers. There is a large overlap between our survey database list and the HimNet subscription list. A total of 258 replies to the survey were received, which account for nearly 40% of our mailing list. Here we briefly report the results of the survey. Although this survey is meant to assess the state of networking and information resources among Himalayan geologists, the ideas and results derived from our survey may

also be useful for development of networks and community services in other fields of geological research and scientific activity.

HimNet (Himalayan Network)

HimNet (HimNet@erdw.ethz.ch) is an e-mail Internet link for researchers working in the Himalayan region (Afghanistan, Pakistan, China, India, Nepal, Bhutan, Bangladesh and Burma). It aims to provide a rapid method of communication and dissemination of information on Himalayan geosciences. HimNet sends direct e-mails to its subscribers. Launched by David A. Spencer in August, 1994, with an initial subscription of 40 people, the number of subscribers has constantly increased over time to 580 (Figure 1).

By May 1996, 27 news packages have been sent to subscribers in 32 countries. Although predominantly related to the geosciences, Himalayan researchers in several other fields (from biology to linguistics) also subscribe to HimNet. Last year, a World Wide Web Home Page (<http://www.lehigh.edu/~inees/himnet/himnet.html>) was set up, and is maintained by Peter K. Zeitler (Lehigh University, USA), allowing access to all the back

issues of HimNet through the WWW or FTP (<ftp://ftp.dharma.geo.lehigh.edu>; User ID: anonymous; Password: your e-mail address; Directory: /pub/himnet).

Virtually all of those who responded to the survey (92%) knew about HimNet; 66% subscribed to it. As for the 34% who did not subscribe to HimNet, the lack of internet connection was cited as the main reason by them (63%). This was especially so in the Himalayan coun-

Figure 1. Subscriptions to the Himalayan Network (HimNet).

tries, where internet connections are not available, or they are too expensive (charged per page) or official permission is required to have an access to e-mail. Other reasons for not subscribing to HimNet included phobias to mailing lists, the fact that the postings took up too much disk space or simply not having time to read it.

The most popular features on HimNet were the Latest Himalayan Papers (91%), Latest Himalayan books (85%) and Conference Announcements (82%). It seems that subscribers use HimNet mainly as source of information, rather than as a medium for discussion. This was also clear from the fact that nearly two thirds of those who subscribed (62%) had never made a contribution to HimNet. Nevertheless, 96% of the subscribers thought that HimNet is a valuable research tool; 61% rated it as excellent and 34% as good.

Himalayan Notes

Himalayan Notes is an international news bulletin on the earth and environmental sciences of the Himalaya-Tibetan region. Founded in early 1993 by Rasoul B. Sorkhabi, it is published twice a year in March and September. *Himalayan Notes* attempts to foster up-to-date information on south-central Asia's geosciences, provide a platform for discussions and exchange of ideas and act as an informational bridge between Himalayan and foreign scientists. It also aims to draw people's attention to the unique geology, environmental problems and global significance of the Himalaya and Tibet. Geoscientists, and others working or interested in the Himalayan-Tibetan region, have subscribed to *Himalayan Notes*. Moreover, some institutions and libraries in Europe, America and the Himalayan countries subscribe to this newsletter. It is also exchanged with some Himalayan periodicals on a regular basis. Regular sections in each issue of *Himalayan Notes* include: In brief (meetings and other short news items), In press (coverage of Himalayan geology in the press), Research line (latest papers, maps, theses, and books), Institutions, Book reviews, Conference reports, Travel accounts and Profiles of Himalayan researchers. At present, *Himalayan Notes* is coordinated by a group of regional editors (in Europe, India, Pakistan, and

Nepal) and a managing editor in the USA.

Nearly 78% of the people surveyed were aware of *Himalayan Notes*, although only 26% subscribed to it. This is mainly because the sending of a small subscription fee for non-USA subscribers was difficult (the overseas bank charges would cost more than the subscription fee!). This problem could be resolved by accepting payment with credit cards. The most popular features of *Himalayan Notes* were the Research Line (read by 98% of subscribers), Conference reports (89%), Book reviews (89%), In brief (86%) and In press (82%). Only half of those subscribed read the travel accounts (52%) and articles about the institutions (48%). Therefore, the subscribers used *Himalayan Notes* mainly as a source of research information, rather than a magazine with feature articles. Similar to HimNet, 57% of the subscribers had never made a contribution to *Himalayan Notes*. Nevertheless, 93% of them thought that it was a valuable information tool and 75% were content with it being published twice a year (18% suggested that the frequency of publication should be increased to four times a year). Although *Himalayan Notes* is predominantly seen as a source of research information, a clear 95% agreed that social issues and cultural aspects of the Himalayan region may be addressed in *Himalayan Notes* from a scientific standpoint and with regards to the natural environment. Most subscribers seem to be satisfied with *Himalayan Notes*, rating it good (68%) or excellent (27%).

The Himalaya-Karakoram-Tibet workshops

Initiated by Michael P. Searle in 1985, the first Himalaya-Karakoram-Tibet (H-K-T) workshop was held in Leicester, Great Britain. Subsequent H-K-T workshops were held in Nancy, France (1986); London, Great Britain (1987); Lausanne, Switzerland (1988); Milan, Italy (1990); Grenoble, France (1991); Oxford, Great Britain (1992); Vienna, Austria (1993); Kathmandu, Nepal (1994); Ascona, Switzerland (1995); and Flagstaff, USA (1996). Proceedings volumes resulting from the H-K-T workshops form an excellent source of up-to-date geological information. These workshops continue to be one of the main forums for pres-

entations on all aspects of Himalaya-Karakoram-Tibet geology.

Virtually everyone who responded to the survey (98%) knew about the H-K-T workshops and 57% had attended at least one of them. The majority of people (89%) who had attended an H-K-T workshop had made a presentation (either oral or poster), indicating that the workshops are clearly seen as a 'participation' event rather than a 'spectator' event. The workshops are also used as an opportunity to meet colleagues (91%), listen to lectures (94%) and discuss Himalayan issues (91%). Although only 56% were interested in the publication of proceedings volumes resulting from the workshops, over 72% stated that they had referred to at least one of the papers published in the past H-K-T proceedings volumes. Nearly half (43%) of those who had attended the workshops considered them too expensive. Nevertheless, 82% considered that the H-K-T workshops mark an important event in their research calendar.

Perhaps one of the most surprising results was that nearly two thirds (65%) suggested that the workshops be held once every 2 years rather than every year (supported by 32%). There were even a few suggestions for holding the workshop every 4 years! The main reason for reducing the frequency of the workshops was that 'because they are too frequent, there is a tendency for delegates to repeat the previous year's talk'. A suggestion was also given that 'because every country is expensive for someone from somewhere, the workshop should (as has been in the last 3 years) be rotated every year to different continents so that all would have a chance to attend. This is only fair'. To date, nine of the eleven H-K-T meetings have been held in Europe. Overall, 57% thought the workshops have been 'good' and 43% rated them as 'excellent'.

International Society of Himalayan Geoscientists

Recently, Rasoul Sorkhabi has brought forward the suggestion that there is a need for the creation of an International Society of Himalayan Geoscientists because, as history shows, scientific disciplines are better developed when their respective communities have become organized, with efficient ways of exchanging information, regular publications and

meetings. 72% of those who responded to the survey felt that it was necessary to establish an International Society for Himalayan Geoscientists. Such a society should mainly be involved in organizing the Himalaya-Karakoram-Tibet workshops (93%), promoting the importance of research in the Himalayan regions (88%) and representing the scientific community (76%). Its other goals may include publishing a newsletter (75%), publishing a research journal (68%) and running an electronic network system (82%). Although not seen necessarily as a 'funding agent', 76% (especially those from the Himalayan countries) suggested that such a Society should try to arrange funds from international or Western world funding agencies to enable students and researchers from the Himalayan countries to attend international meetings. Half (53%) of those who supported the idea of founding an International Society for Himalayan Geoscientists indicated that they were willing to get involved in its establishment.

However, there were also some arguments against the formation of the Society. For example: 'Such organizations divert energy away from research'; 'Official organizations actually hinder cooperation, especially between young and old scientists'; 'No need for another society. A formal organization would not improve our situation unless a lot of effort and time is devoted to it.' Most of those who were against the formation of a Society were the more established and experienced Himalayan geologists from Europe or the USA, while virtually all of the researchers from the Himalayan countries supported the idea.

Summary and concluding remarks

(1) Overall, the Himalayan research community appreciate the importance of networks and information resources available to them; however, only a minority of them actively contributed to the community services.

(2) Both HimNet and *Himalayan Notes* are relatively newcomers to the scene of Himalayan research. HimNet is free of charge, while *Himalayan Notes* requires subscription fees to cover the cost of printing and postage. This, and the fact that HimNet is a faster method of communication are the main reasons for the large disparity between the numbers of their subscribers. Nevertheless, both of these media enjoy large support. The subscribers use them largely to obtain information rather than for discussion. Since both HimNet and *Himalayan Notes* are produced by volunteer efforts of several individuals, their future activity cannot be ensured unless they are run by some commercial body or rotated voluntarily among active Himalayan researchers. The establishment of an International Society for Himalayan Geoscientists would provide suitable channels for such volunteer efforts.

(3) The Himalaya-Karakoram-Tibet workshops are seen as the main gathering opportunity for most Himalayan researchers. Nevertheless, the majority of the surveyed people thought that these annual workshops are too frequent. Although the idea of holding the H-K-T workshops every two years needs to be closely examined, it should be noted that over the past decade, these annual meetings have become increasingly popular and have produced a large amount of geological publications on the Himalayan region (few tectonic regions and geological workshops have been so prolific).

(4) Most researchers support the idea for the creation of an International Society of Himalayan Geoscientists. Nevertheless, to succeed it would require a great deal of time and energy. As history shows (for example, the Geological Society of London was founded in 1807 by George B. Greenough; the Geological Survey of Great Britain during the 1830s mainly through the efforts of Henry De la Beche; the Royal Geographical Society in 1830 under the leadership of Sir Roderick Murchison and the US Geological Survey in

1879 by Clarence King and John Wesley Powell) most of the scientific and professional societies were founded through the cooperation of a few pioneer, like-minded individuals, not necessarily the consensus of a whole community. Indeed, the majority support of the Himalayan research community for founding a Society is a very positive sign of its success. Through determination and devotion of founders during the early years of a Society and providing useful services, scientific societies have filled a niche among their communities and succeeded. There is no reason to believe that the establishment of the suggested International Society of Himalayan Geoscientists should be any different from past historical experiences. Opportunities for such ventures are open to all Himalayan researchers in all countries. There are already several networks and resources, such as HimNet, *Himalayan Notes* and the H-K-T workshops, as well as other specialized periodicals such as the *Journal of Himalayan Geology* (published semi-annually by the Wadia Institute of Himalayan Geology, India) and the *Himalayan Research Bulletin* (two semi-annual periodicals in North America and Europe which focus on social sciences). Although all these resources can form vital elements of any international society, they are currently scattered mini-islands; they can better develop under an umbrella of an international society with high scientific and democratic standards.

ACKNOWLEDGEMENTS. We would like to thank all those who responded to the Survey of Himalayan Resources.

David A. Spencer is at the Institute of Geology, Swiss Federal Institute of Technology, CH-8092, Zürich, Switzerland, and Rasoul B. Sorkhabi is at the Department of Geology, Arizona State University, Tempe, Arizona 85287-1404, USA.

Optical astronomy using radio techniques: Imaging Capella with unprecedented resolution

P. Venkatakrishnan

Radio astronomers fully vindicated the oft-quoted maxim that necessity is the mother of invention when they went about the task of imaging celestial radio sources. What may seem to be a trivial job in optics, e.g. imaging the sun on to a white screen and looking at the sunspots, would require a radio 'lens' or 'mirror' that is over 100 m wide. Likewise, a 10 km wide lens would be needed to form an image of Jupiter in microwave radiation. This is because electromagnetic waves bend around obstacles (the phenomenon of diffraction) and fail to come to an exact focus. This fuzziness increases with the wavelength of the radiation. Light waves, being a million times smaller than microwaves, can be 'tamed' by lenses that are a million time more compact than the sizes mentioned above. Faced with this immense problem, radio astronomers since the fifties have followed the Nobel prize winning lead of Martin Ryle at Cambridge. They build up their images using a collection of smaller antennas distributed over large areas. The signals from each pair of antennas are multiplied together and averaged in time, yielding a quantity called the correlation. The separation of the antennas expressed in multiples of the wavelength is called the spatial frequency. The set of correlations for various spatial frequencies are then fourier transformed (a mathematical operation that does a sort of book-keeping on the number of waves present in a pattern of signals). The resulting function gives the brightness distribution of the source, as a function of the angular position. The theorem connecting correlations in the wavefront, with brightness distribution on the source, is called the van Cittert-Zernike theorem and was developed for optics! Formally, this technique of imaging is called aperture synthesis.

There is nothing in principle that prevents optical astronomers from using this technique (although it seems a somewhat round about way of imaging as compared to more conventional ways). The correlation is obtained by combining the beams from the two apertures and forming an interference pattern (as did the great

optical physicist Michelson when he measured the diameter of some stars at the turn of the century). The larger the correlation, the deeper will be the modulation in the interference fringes. In practice, several factors inhibit the realization of this method. The path difference between the two apertures must be shorter than the longitudinal coherence length, otherwise the fringes will get washed out. This is the length occupied by that number of waves which is equal to the ratio $\lambda/\Delta\lambda$, which is the number of bandwidths present in one wavelength. For example, the coherence length is a mere 2.5 μm for a 100 nm bandwidth centered around 500 nm. The mechanical tolerance of the experimental setup is restricted to micrometre accuracies over the baselines (separations of antennas) that are used. If one wants to escape this constraint by using a very small bandwidth, then one will need to spend a lot of time to collect the required number of photons to achieve decent signal to noise ratios. However, the fluctuations in the atmosphere (that produce twinkling of starlight) allow only about 10 milliseconds to obtain the interference pattern. If one thinks that having large apertures would do the trick, then the spatial extent over which the standard deviation of the atmospheric fluctuations are within a reasonable limit (say, a quarter of the wavelength) is only 10 cm. Thus, having apertures larger than this limit does not help. So aperture synthesis at optical wavelengths is an extremely demanding enterprise and would interest the astronomers only if they need angular resolutions much beyond the diffraction limits of large single telescopes. A few groups of astronomers have been able to interfere light from two separated telescopes and use the depth of modulation of the fringes to resolve binary stars that are separated by a few hundredths of arcseconds. The prospect of producing a genuine interferometric image seemed bleak. But not anymore. For this feat has recently been achieved by John Baldwin and coworkers at Cambridge, UK (*Astronomy and Astrophysics*, 1996, 306, L13-L16).

The extra requirement to form an image

is the knowledge of the fourier phase of the target source. The fourier transform of a symmetrical object is a real function which comes with a plus or minus sign. Asymmetric objects yield complex fourier transforms needing a phase angle anywhere between 0 and 360 degrees for full specification. The fourier phase (or visibility phase) is then the argument of the complex fourier transform. The modulus of the transform is called the fourier amplitude, or visibility amplitude. It represents the contrast of variations in the object at the given spatial frequency. The phase represents the morphology, or positional information of the variations at that spatial frequency. For example, an unresolved object at the centre of the field would continue to have undiminished visibility amplitude of unity at the largest separation of the antennas (or telescopes), corresponding to the largest spatial frequency. The phase would be zero degrees all through. A resolved object would have an amplitude that goes to zero at a spatial frequency corresponding to the inverse of the angular size of the source, while the phase switches from 0 degrees to 180 degrees at this spatial frequency. Knowledge of phase is crucial for imaging, since it provides basic information on the morphology of the object. For example, when the fourier amplitudes of a binary source (shown in Figure 1 a) are randomized, while retaining the phases, the object in Figure 1 b is obtained which is still a binary, albeit with different contrast. On the other hand, if the phases are randomized, keeping the amplitudes intact, the resulting image (Figure 1 c) is scarcely recognizable. Actually, what is needed is the relative phase between two spatial frequencies. Because of turbulence, it is impossible to 'freeze' one phase. So we require simultaneous measurements of three phases, hence we need at least three antennas or telescopes. If the turbulence introduces a random phase in antenna 2, it has opposite effects on baselines 12 and 23. The sum of phases on 12, 23 and 31—the so-called closure phase, is thus an intrinsic property of the object with random properties of the medium cancelling out.

RESEARCH NEWS

The COAST (Cambridge Optical Aperture Synthesis Telescope) instrument developed by John Baldwin and his group has four telescopes, of which three were used to image the star Capella. These telescopes are simple in design. The object is tracked by siderostats (flat mirrors rotating about an axis parallel to earth's rotation axis and inclined suitably to send the reflected beam along a fixed direction). These siderostats feed horizontal telescopes. This design has the great advantage that long moving parts are avoided, thereby achieving the stringent limits of mechanical accuracy set by the longitudinal coherence length. Light from each telescope is brought along evacuated pipes into a thermally insulated interference station (actually a grass covered bunker!). Pupil plane interferometry is employed rather than interference in the image plane. The advantage is that the width of the fringes can be controlled independent of the focal length of the imaging system. This is particularly useful for photon starved observations. In the COAST setup, the images of the interfering pupils are kept parallel, so that there is uniform illumination at the interfering plane. The interference is then detected by introducing a periodic path delay of about $50\text{ }\mu\text{m}$ sweep in each arm to produce a corresponding modulation

in the combined light. This modulation is detected by an avalanche photodiode operating as a photon counter. The beauty of the arrangement is in the modulation of the fringe pattern of each pair of telescopes with a distinct periodicity, viz. 238, 477 and 715 Hz respectively. So, a single detector can record all the fringe visibilities, which are encoded in distinct temporal frequencies. The triple product of the three complex visibilities, corresponding to the three baselines can thus be conveniently recorded. The argument of the resulting complex number is the closure phase. Once the closure phase is known, the radio astronomers know how to reconstruct images from the visibility amplitudes and closure phases of a set of sparsely distributed baselines. The COAST experiment used interspersed observations of a single star to calibrate the visibility amplitudes.

Because of incomplete coverage in the spatial frequency domain, the reconstructed images will have many 'side lobes', which are carefully removed by an algorithm called CLEAN, which is very popular among radio astronomers. The projections of the three telescopes on to the sky plane move around with the rotation of the earth and a nice spatial frequency coverage can be obtained in this way. Two images of Capella were

obtained for two epochs separated by 15 days. The relative positions of the components lie on an orbit agreeing with that predicted by other measurements. The separation of the binary is in the region of 50 milliarcseconds, while the position angle changed by about 50 degrees during the 15 day interval (see Figure 2).

Apart from the fact that this is the first genuine optical interferometric imaging of a celestial object with separated telescopes, it also provides an exciting peek into the future of optical astronomy. Conventional astronomers seek to build larger and larger telescopes to look at very faint objects. Eventually, when the mechanical problems of large telescopes become unsurmountable, they will have to fall back upon the concept of telescope arrays which Antoine Labeyrie, John Davis, Michael Shao, John Baldwin and their ilk have courageously tried to advance. Of course, it has not been easy for the COAST group (see *Physics Today*, April 1996, pp. 17-18). The project meth-

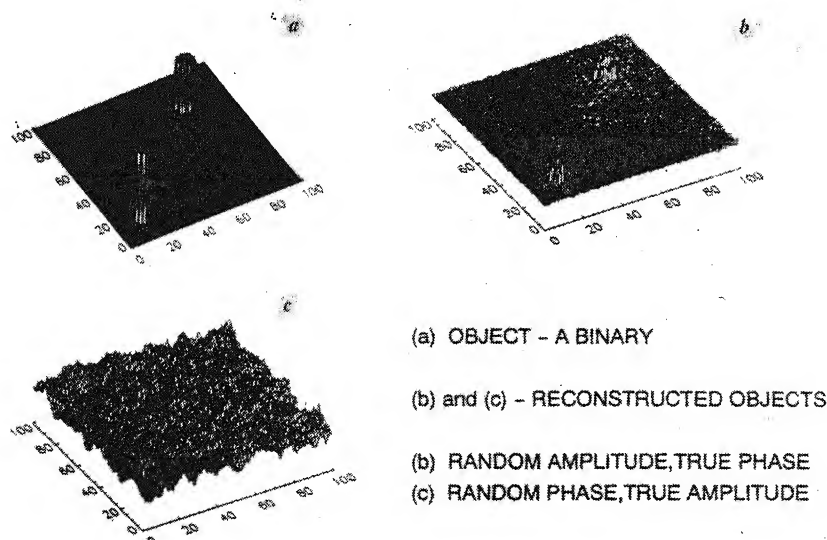

Figure 1 a-c. This figure shows the importance of visibility phase. The object of Figure 1 a was Fourier transformed. The Fourier phases were first left untampered. The Fourier amplitudes were replaced by random numbers, with total power being conserved in the Fourier domain. The reconstructed image is shown in (b). Next the Fourier amplitudes of the original object were retained while the Fourier phases were replaced by random numbers. The result of reconstruction is shown in (c). (Generated by R. Sridharan, Indian Institute of Astrophysics.)

odology adopted by Baldwin is worth special attention, especially for younger persons embarking on new techniques. He started with experimenting on a few masks placed over a single telescope and gradually worked his way up to the current achievement. The paper which

reported this achievement has a large number of authors from several institutions—a model for successful cooperation that merits special mention. We can expect several new discoveries when the sensitivity and resolution of this technique improve, and when the several other con-

tenders in this game achieve similar successes.

Volatile oil constituents and wilt resistance in cumin (*Cuminum cyminum* L.)

Cumin cultivation has received a serious threat from wilt disease which devastates the total standing crop. Screening of lines against cumin wilt under artificial/field conditions indicated that UC-198, UC-199 and RZ-19 have shown fairly good tolerance to wilt¹. Different entries of cumin were evaluated for volatile oil contents and correlated with wilt incidence. To understand the role of volatile oil in disease resistance at the molecular level, the volatile oil was fractionated on GLC and correlation between volatile oil constituents and wilt resistance was determined.

Fourteen entries of cumin were grown at Agriculture Farm of S.K.N. College of Agriculture, Jobner under All India Coordinated Varietal trial. The volatile oil contents from these entries were evaluated using Clevenger apparatus². The volatile oil was made moisture-free by using anhydrous sodium sulphate and

stored in a glass vial. These samples were subjected to gas chromatographic examination as described earlier³. The identity of the constituents was ascertained by comparison of relative retention time with authentic standards. The percentage of oxygenated compound and hydrocarbons was recorded.

The negative correlation between volatile oil contents and wilt incidence (Figure 1) suggests that the variety with high volatile oil contents is less prone to wilt which was not true in all cases. The anti-microbial property of volatile oil was also reported by other workers^{4,5}. Earlier we reported that the growth of wilt pathogen, *Fusarium oxysporum* was inhibited in presence of volatile oil of cumin. The effectiveness of inhibition varies from variety to variety⁶. To understand it at the molecular level, the main components of volatile oil of some varieties of cumin were determined. Volatile oil of cumin

consists of a mixture of hydrocarbons (terpenes, sesquiterpenes, etc.) and oxygenated compounds (alcohols, ester, ether, aldehydes, ketones, lactones, phenols, etc.). Of these, the oxygenated compounds are the principal odour carriers, although the terpenes and sesquiterpenes too contribute to some degree to total odour and flavour. These components are separated on GLC on the basis of their partition coefficient. The hydrocarbon components and oxygenated compounds are having marked difference in the retention time due to polarity differences. The main constituents of volatile oil of cumin are cuminaldehyde, cuminyl alcohol, terpenes, p-cymenes, pinenes, etc. The first two components are oxygenated compounds and the last three are hydrocarbon compounds. So cumin oil has two types of

Table 1. Volatile oil constituents of cumin and relative wilt resistance

Entry	Volatile oil constituents (%)		Ratio of a : b	Relative wilt resistance (0-9 scale)
	a	b		
UC-199	76	21	3.61	1-2 (R)
UC-198	55	38	1.44	1-2 (R)

SCIENTIFIC CORRESPONDENCE

components, i.e. oxygenated compound and hydrocarbon compound. The percentage of volatile oil constituents and the ratio of oxygenated components : hydrocarbons were found correlated with wilt resistance (Table 1); the varieties having high ratio of oxygenated components : hydrocarbons are more resistant to wilt compared to those with lower ratio. Thus oxygenated compounds, i.e. cuminaldehyde and cuminyl alcohol appear responsible for resistance to wilt.

Applications are invited for FACULTY POSITIONS in the Department of Organic Chemistry at the level of ASSISTANT PROFESSOR in all areas of organic chemistry, including emerging interfacial areas such as organic chemistry/biology, organic chemistry/materials science, etc.

Qualifications and experience

i) Ph D in Organic Chemistry or a related discipline, ii) a distinguished record of publications; and iii) 3 years of post-doctoral teaching/research experience (relaxable in exceptional cases). Applicants must be able to pursue an independent programme of original research and committed to teaching and scholarship.

Emoluments: Rs 10,250 p.m. in the minimum of the scale of Rs 3700-5700.

Details and application form can be obtained on a request accompanied by an IPO for Rs 10 drawn in favour of Registrar (free of cost to SC/ST candidates on production of caste certificate) along with a self-addressed stamped (Rs 2) envelope of the size 28×18 cm on or before 9 September 1996.

Completed applications along with copies of certificates, publications and a research plan for the next few years should reach the Registrar on or before 20 September 1996. Candidates from abroad may send their applications on plain paper with all relevant information and references. At least three Referees may be requested to send their considered reports to the Registrar simultaneously.

For further information please contact by e-mail scn@orgchem.iisc.ernet.in. Applicants are also welcome to visit the Organic Chemistry home page at the URL <http://144.16.77.27/>

Heavy rainfall during monsoon season: Point and spatial distribution

P. R. Rakhecha and P. R. Pisharoty

The daily rainfall records of about 5000 stations in India, during the monsoon periods of several decades, have been examined for occurrence of heavy rainfall. The point values of (i) the highest annual rainfalls, (ii) the highest rainfalls of one, two, and three day durations, and (iii) the highest hourly values, are presented in the form of tables and charts. The highest depth-area-duration values for twelve storm-centres are also given.

AN important feature during the Southwest and Northeast monsoon seasons of India is the occurrence of heavy rainfall associated with certain meteorological situations all over the country. Persistent copious rains throughout a season are associated with orographic lifting of moisture-laden winds, heavy rains for periods of days with cyclonic storms and the short period heavy falls with intense thunderstorms. The Western Ghats is an excellent example of an area where heavy rainfall occurs due to orographic effects. Rainfall caused by a depression is as high as 40–80 cm per day. Many stations have recorded their mean annual rainfall in a single day.

A great proportion of variability of rainfall in India is related to the occurrence and intensity of extremely heavy rainfall events and as such there is a need to know the magnitudes of heavy rainfall events over different parts of the country. Discussions on heavy rainfalls are also of great importance in the designing of water projects. The spatial distribution of point and areal values of highest rainfalls over the Indian region on the basis of historical rainfall data of a large number of stations, are summarized in this paper.

measurement sites were established throughout the country. At present there are about 5480 rainfall stations spread all over the country. The daily rainfall data of these stations are available in digital form at the National Data Centre of the India Meteorological Department, at Pune.

Causes of heavy rainfall

Heavy rainfalls occur over different parts of the country and are associated with:

- i) Formation and subsequent movement of cyclonic disturbances across the country
- ii) Orographic lifting of moisture air as it rises along the slope of a mountain barrier across the air stream
- iii) Breaks in the monsoon, when the rainfalls are confined to the Himalayas and the Indian regions close to it.

The cyclonic disturbances are low pressure systems in which the associated wind circulates in a counter clockwise direction in the Northern Hemisphere. The

Rainfall stations in India

Rainfall measurement in India was started towards the end of the 18th century. The first recorded data were obtained at Calcutta in 1784 followed by observations at Madras from 1792, Bombay from 1823 and Simla from 1840. However, the recording of rainfall at a large number of stations was started from the middle of the 19th century. The need for increasing the networks of rainfall sites for hydroclimatic purposes was felt after 1947 and, as a result, extensive networks of rainfall

The authors are in the Indian Institute of Tropical Meteorology, Pune 411 008, India.

GENERAL ARTICLES

criteria for describing the cyclonic disturbances over the Indian sea areas are as follows:

System	Wind speed in circulation
Low pressure	< 20 knots
Depression	20–33 knots
Cyclonic storm	34–47 knots
Severe cyclonic storm	> 48 knots

When the maximum wind in the circulation reaches 64 knots or more, the system is called a severe cyclonic storm with a core of hurricane winds.

During the SW monsoon period the cyclonic disturbances (mainly depressions with associated winds of 20–33 knots) form over the north of the Bay of Bengal to the north of 18°N and move in a northwesterly direction across the country. Depending upon the tracks

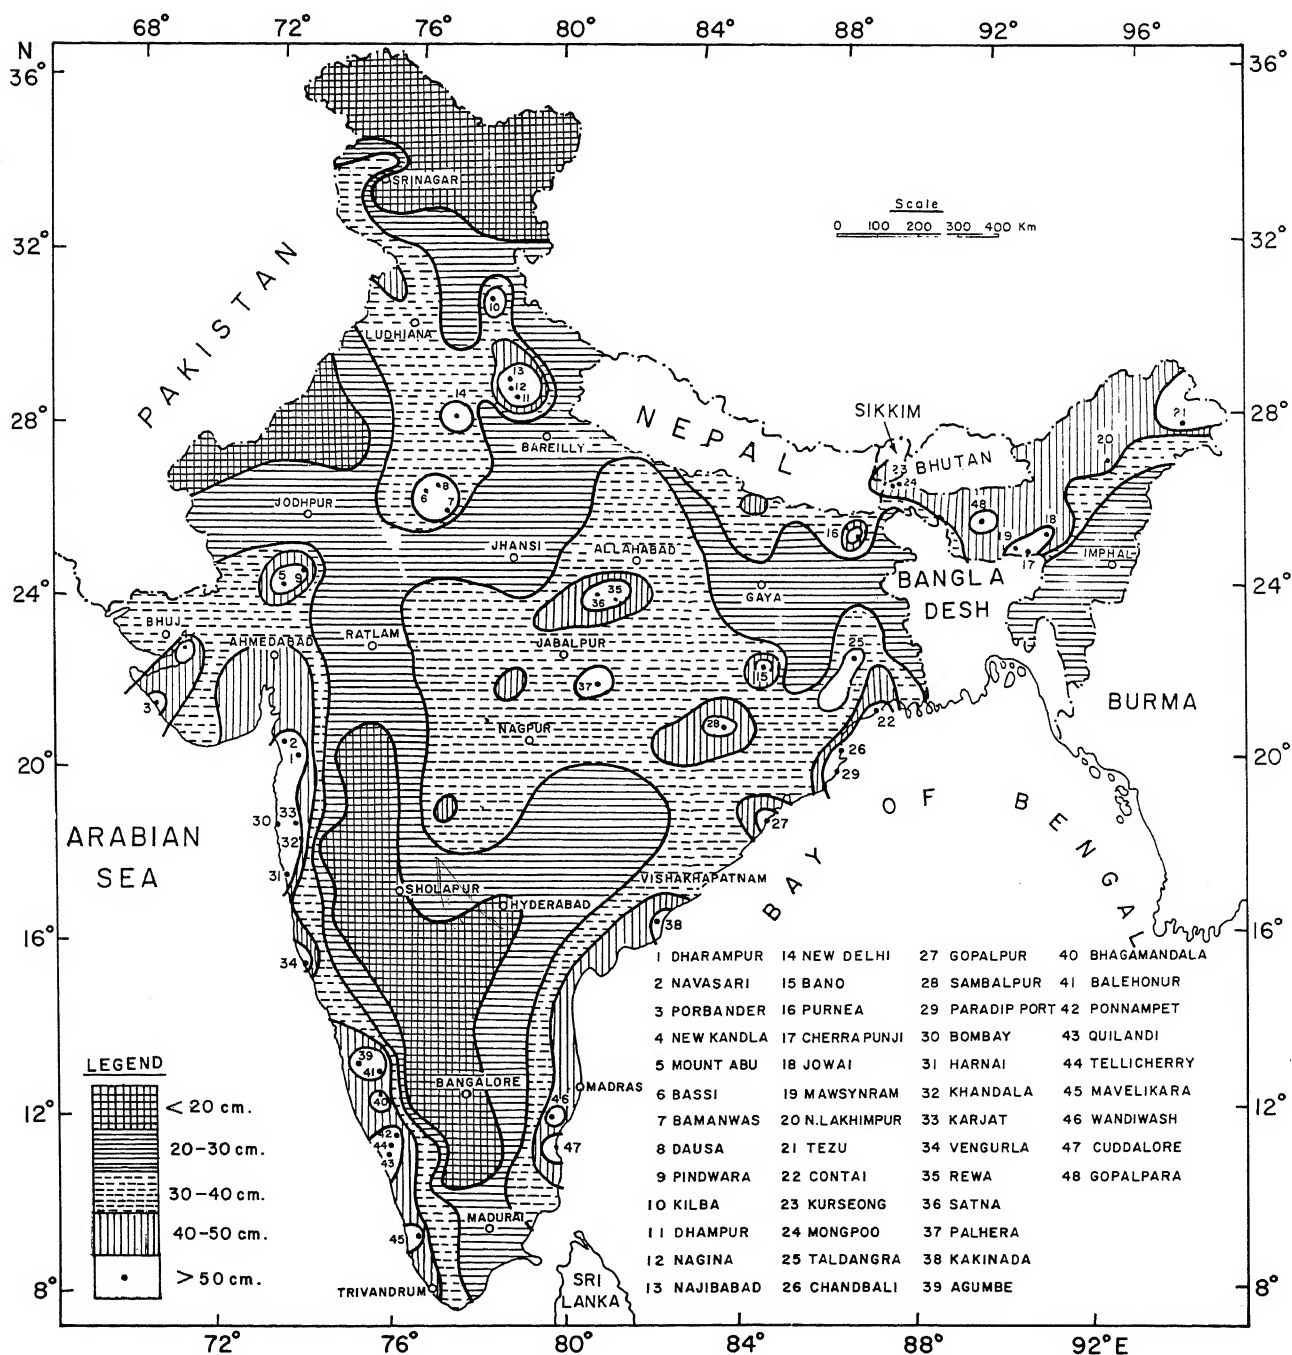

Figure 1. Highest rainfall for 1-day duration (period 1875–1982).

of these disturbances, heavy rainfall occurs in the regions which are exposed to these disturbances. Rainfall caused by such depressions can range from 40–80 cm per day. The maximum rainfall recorded in the plains during these disturbances are 90 cm in one day at Purnea in Bihar and 99 cm in one day at Dharampur in Surat district of Gujarat. The average annual frequency of monsoon depressions are 7, of which about 1 occurs

in June and two each in July, August and September. During the active monsoon the strengthening of the Arabian Sea current results in heavy rainfall along the west coast of the peninsula and on the Western Ghats. When a depression forms in the Bay of Bengal often the Arabian Sea monsoon current is strengthened; it causes heavy rainfall over the Western Ghats; due to orographic lifting of the moisture-laden winds.

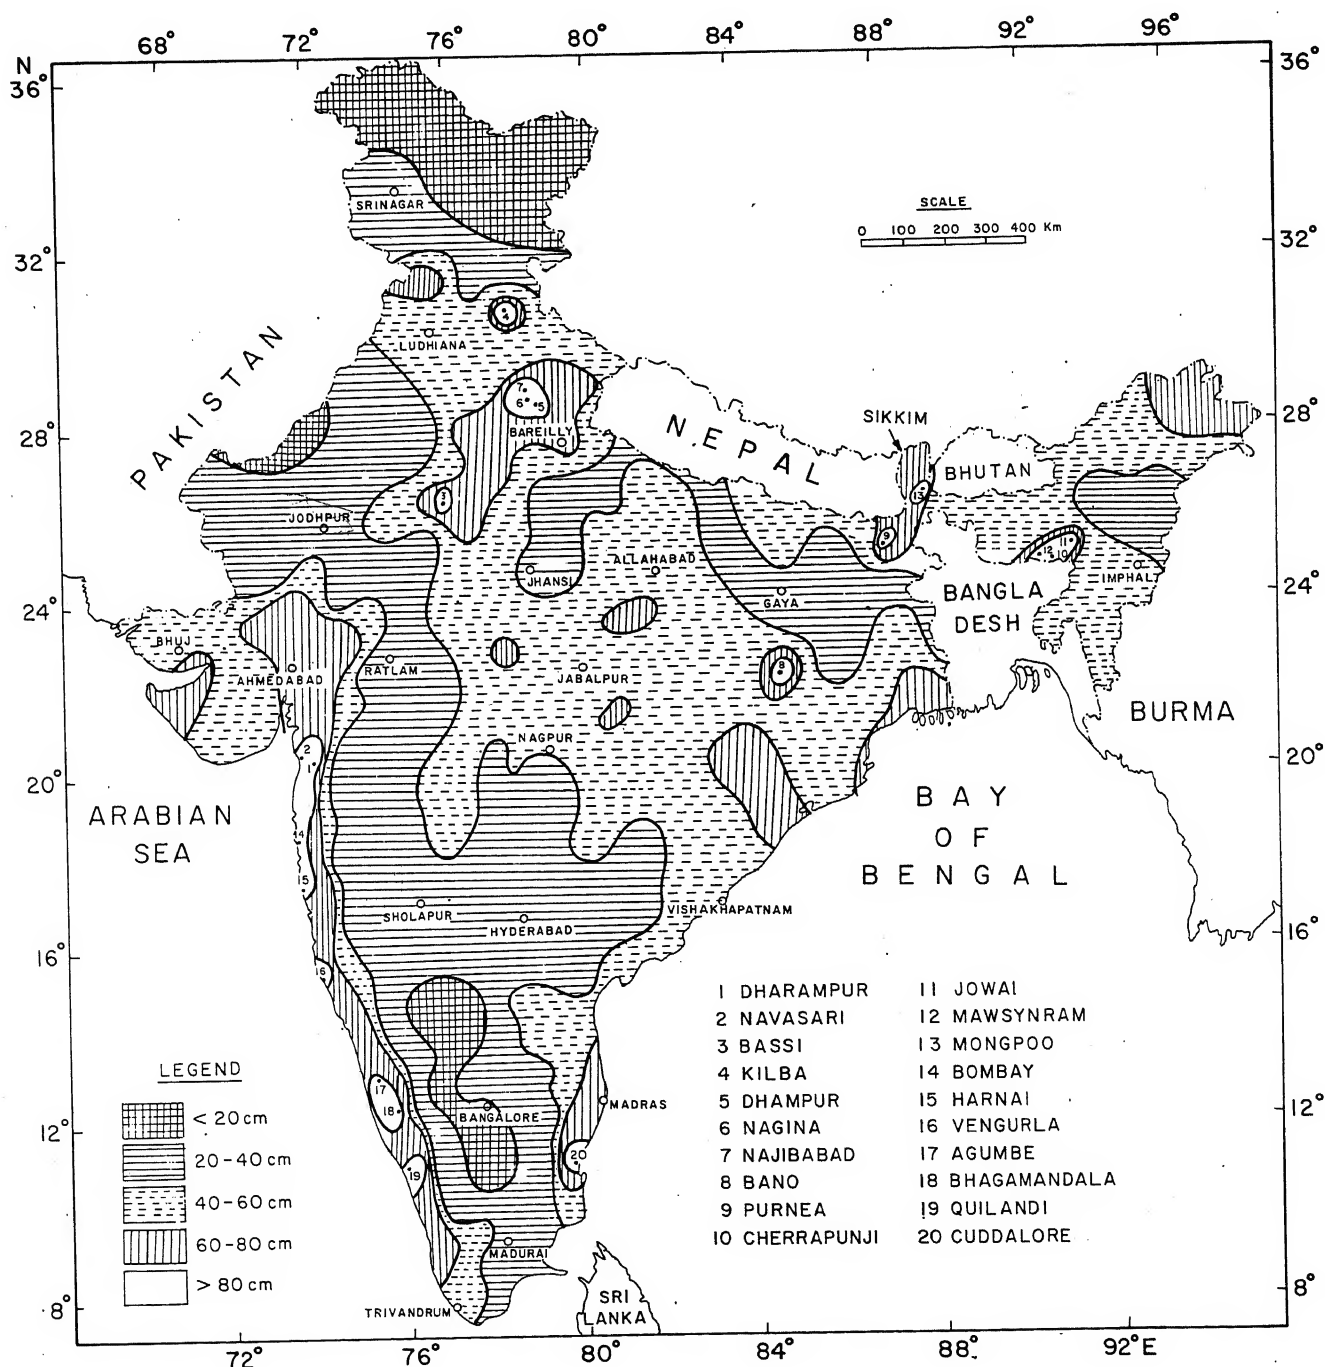

Figure 2. Highest rainfall for 2-day duration (period 1875–1982).

GENERAL ARTICLES

Rainfall during the monsoon season is not continuous but alternates with active and break monsoon conditions. During a 'break' the seasonal monsoon trough of low pressure shifts northwards from its normal position to the foothills of Himalayas where heavy rainfalls occur.

During the pre-monsoon and post-monsoon months, tropical storms form in south Bay of Bengal and Arabian Sea. Many of these storms move inland and cause heavy to very heavy rainfall along and near their tracks over the southern parts of India.

The magnitude and frequencies of the heavy rainfalls, however, differ widely because of variations of physiography and atmospheric features.

Highest annual rainfalls

The data on annual rainfall, from about 4000 stations, show that there are about 14 stations in the country where mean annual rainfall is 500 cm or more (Table 1). Of these 14 stations, 4 stations (Buxa, Cherrapunji,

GENERAL ARTICLES

Denning, Mawsynram) are located in northeast India and the other 10 stations are located in the Western Ghats of Peninsular India. Apparently, very high annual rainfalls occur in the hilly regions. Mawsynram in the Khasi hills and Agumbe in the Western Ghats of south India have received the highest annual mean orographic rainfall of about 1141 cm and 828 cm respectively.

Highest daily rainfalls

Heavy to very heavy rainfall for periods of days occurs associated with the movement of cyclonic disturbances from the Bay of Bengal and the Arabian Seas over India. The daily rainfall data for about 300 stations for the period 1875 to 1982 were used to determine the

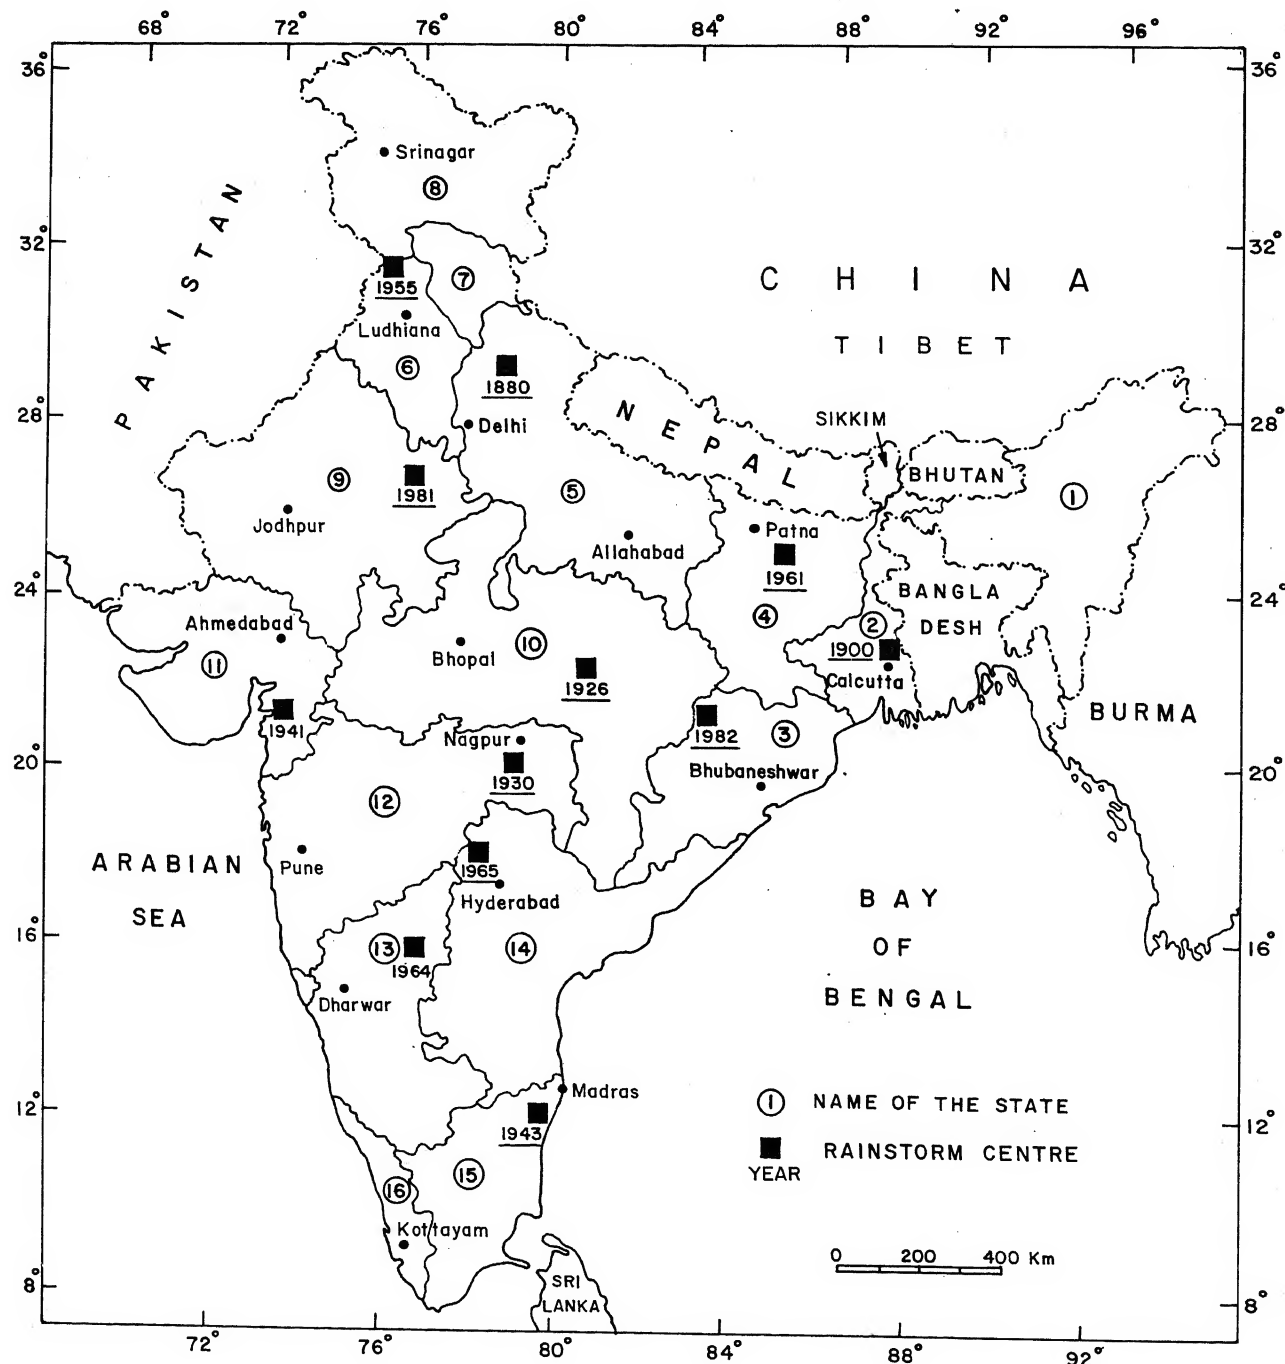

Figure 4. Locations of rainstorms centres.

highest rainfall values of one, two and three-day durations. It may be pointed out that there is an element of randomness in the magnitudes of the highest rainfall recorded even though observations are available for over 100 years. But when the data of all stations are examined together, some broad patterns emerge. The highest rainfalls for 1, 2 and 3-day durations were plotted separately on a large scale map of India and isolines drawn at suitable intervals. The resulting spatial patterns are shown in Figures 1 to 3.

Figure 1 shows the pattern of the highest 1-day rainfall across the Indian region. The isohyets of the highest 1-day rainfall range from less than 20 cm over large parts of the interior peninsula, the arid region of the west Rajasthan and northeast of Jammu and Kashmir to over 40 cm on and near the coastal strips including the Gujarat and Saurashtra coasts, the mountainous regions of the Western Ghats, the hills of Assam and the foothills of the Himalayas. Heavy rainfalls exceeding 30 cm in 1-day have also occurred over the central parts

of India lying between 19°N to 25°N and 70°E to 84°E. Some places on or near the coasts for example, Bombay, Harnai, Cuddalore, Wandiwash, Kakinada, Paradip, Gopalpur and Contai and some places in the hills such as Agumbe (Karnataka), Mount Abu (Rajasthan), Khandala (Maharashtra), Cherrapunji, Jowai and Mawsynram have recorded 60 to 100 cm rainfall in 1-day.

The spatial patterns of 2-day and 3-day highest rainfalls are shown in Figures 2 and 3 respectively. The highest recorded rainfall values of 1 to 3-day durations for some coastal as well as for high and low level stations are given in Table 2.

The highest rainfall values represent only small areas around the recording points. The table shows that Cherrapunji (mountainous area) recorded the highest rainfalls of 104 cm, 165 cm and 224 cm in 1, 2 and 3-day periods respectively. Dharampur (plain area) in south Gujarat recorded the highest rainfalls of 99 cm, 126 cm and 145 cm in 1, 2 and 3-day periods respectively. It was found that a cyclonic disturbance lasting for 6 days ravaged the area at that time and provided ideal conditions for spectacular falls.

Highest areal rainfalls

Heavy rainfalls are most important when the period extends to days and the area covered is extensive. Cyclonic disturbances (depressions/cyclonic storms) cause widespread and intense rainfall in areas over which they travel. During the SW monsoon season, the maximum number of cyclonic storms (mainly depressions) from over north Bay of Bengal which have usually a life period of 4 to 5 days. After formation they travel in a northwesterly direction across the country. Rainfall occurs in the region along and near the tracks of these moving storms. The total areal covered by the rainfall reaches about 400,000 km² and point rainfall ranges from 40 to 80 cm in 1-day. These monsoon depressions play a very critical role in the distribution of monsoon rains over the country.

The tracks of these disturbances in July and August are very significant. Their tracks in these two months are concentrated into a comparatively narrow band, indicating a certain amount of regularity in their movement during this period. During September, the spread of the storm tracks is noticeable and it increases further during the post-monsoon month of October. The larger spread of storm tracks indicates the possibility of heavy rainfall occurring not only in the northern river catchments, but also in the southern river catchments during September and October. Cyclones occur, some of them of severe intensity, during the premonsoon (March–May) and postmonsoon (October–December).

Recently, on the basis of rainfall data from the 15 highest storms that occurred in different parts of India, areal distribution maps of maximum 1-day, 2-day and 3-day rainfalls were prepared by IITM¹. Based on the

depth-area-duration (DAD) method, the largest average depth of rainfall that fell over various sizes of area during 1, 2 and 3-day durations are given in Table 3. For a 5000 km² area the maximum rainfall from these 12 storms varied from 22 to 65 cm for 1-day, from 27 to 97 cm for 2-day and from 38 to 117 cm for 3-day duration. The locations of the storms are shown in Figure 4.

The primary weather feature responsible for causing the above heavy rain spells were depressions/cyclonic storms from Bay of Bengal. The spatial pattern of rainfall for 3-day duration for the July 1941 storm is shown in Figure 5. The centre of the storm was located at the Dharampur station in the Gujarat region, which recorded 99 cm on the first day, 127 cm on the first and second day together, and 145 cm on the three days put together.

Highest hourly rainfalls

The highest 1-hour rainfall values for some stations are shown in Table 4. These figures represent intensities only over small areas around the recording points; for turbulence and exposure characteristics of the measuring gauge can vary even over a small distance of a few metres. Most of the very high 1-hour falls have occurred in the coastal and mountainous areas. The highest 1-hour fall, 12.9 cm occurred at Bombay.

Linking technology development with production – A methodology and case histories

S. C. Gupta

Significance and the process of linking technology development with production in the innovation chain are brought out. The individual and joint roles and responsibilities of the development and production agencies are identified. The methodology and attitude used for fruitful interaction between the development teams of VSSC and the different production agencies are illustrated by case histories of different items. A case of unsuccessful production is also presented to bring out the importance of market forces.

GLOBALIZATION of Indian economy has made pursuit of competitiveness by industry of the country an imperative. Generation and utilization of know-how for improved products and services contribute greatly to competitiveness. For this purpose, there has to be a strong team-work between the research and development teams – which generate the know-how, and the production teams – which utilize the know-how. Whether or not the two teams belong to the same corporate body, the team-work has to be meticulous. The data for India on expenditure on R&D by industry, utilization of know-how generated in India and import of know-how brings out unambiguously that there is little support for the generation of know-how in India and most of the need is met by import. India has a vast R&D infrastructure and substantial R&D manpower. India has also achieved impressive successes in developing and utilizing know-how in a number of important fields, such as space and agriculture. Thus, there is inherent capability. What is lacking is an effective harnessing of the inherent capability.

One of the most important functions of research and development is to generate know-how for transfer to industry for production of new and improved goods and services. Acceptance of the know-how by industry spurs R&D. However, acceptance depends on the techno-economic features of the know-how. The know-how has to be mature and comprehensive enough for smooth production. The respective responsibilities of the R&D and production teams during the transfer, production and marketing activities are to be identified clearly and discharged fully. Near certain prospects of attractive profits to the production agency strengthen acceptance. The R&D team can provide adequate information and

confidence on the first two features of the offered know-how. As the profit potential of the know-how also depends on factors such as market forces, beyond the control of laboratory and industry, the information generated by the R&D team has to be supplemented.

Lack of confidence in the dependability of the technical information provided by the R&D team is often a stumbling block. While critical analysis of the information by independent analysts and consultants may generate some confidence, naturally the clinching assurance comes from the earlier experience of working together successfully. An offer of systematic methodology of know-how transfer and team-work can also generate confidence, specially when past experience in know-how transfer from an R&D team is limited or non-existent. Since the production team is also intimately involved in the transfer of know-how, careful selection of the production team(s) is also critical for the success of the transfer process.

One of the motivations of technology development teams is to see the fruits of their labour being utilized by the needy users. Achieving higher performance and greater reliability at costs affordable to a large body of users is well worth the painstaking and innovative efforts to improve design, fabrication and testing processes. However, without ensuring production with specified quality and in needed quantities at required schedules and at competitive costs, the development process may not progress beyond the development laboratory and reach users. As a result, the developed product may eventually go to a museum rather than to the market place. Just as a development laboratory is the most likely place for innovation and technology development, a manufacturing facility is the most suitable place to do justice to the exacting demands of production. The development laboratory and manufacturing facility thus

S. C. Gupta is in the Vikram Sarabhai Space Centre, Thiruvananthapuram 695 022, India.

form indispensable links in the innovation chain. The user forms the third link in the chain. Vigorous interaction among the three links contributes greatly to the success of the innovation cycle. What needs to be done to bring about vigorous and fruitful interaction between a development laboratory and a manufacturing facility is the subject of this paper.

This paper draws on the experience of the Vikram Sarabhai Space Centre of the Indian Space Research Organization in technology development and transfer. Identified are the features of mature and comprehensive know-how, respective responsibilities of the R&D and production teams and selection process of production team(s). A few case histories covering both successful and unsuccessful production are also presented to illustrate and clarify the issues.

Features of know-how

To enable taking up production, the production team requires the following essential details:

(i) A mature design, based on which the product has been made and has undergone successfully independent rigorous performance evaluation and service environment-endurance tests. Product should have been made in enough quantities to establish repeatability of performance within the identified tolerance band. While the design methodology does not have to be revealed, full description of materials of construction, component values and permissible tolerances, etc. is essential. A comprehensive guideline is given in ref. 1. (ii) Data on performance evaluation and environmental endurance test results. (iii) Drawings and explanatory notes using which the product can be made by a team skilled in the relevant fields, without the direct participation of the development team. Those components or processes are to be highlighted, successful realization of which requires unusually high skills of craftsmanship, meticulous quality checks and/or specialized facilities. (iv) Information on the required raw materials and components and their quality standards and sources of supply. (v) Information on quality control processes to be adopted during the various phases of production. (vi) Information on equipments for production, quality control, performance evaluation and environmental tests. (vii) Information on maintainability, servicing, essential spares, and recalibration procedures, wherever applicable. (viii) Data on consumption of energy and raw materials in the production of the product, wherever applicable. (ix) Information on effluents and their likely impact on environment and ecology with or without effluent treatment. Process and cost of effluent treatment, if any. (x) Information on hazards of any kind, if any, in the production process and effluent treatment. (xi) Informa-

tion on assured demand for the product in terms of quantity, quality and pricing over a reasonable period of time or till the product is likely to become obsolete. (xii) Information on likely time by which the product will become obsolete.

The development team should be able to generate adequate data on the first five items listed above. Data on the rest may have to be generated jointly by the development and the production teams and the users, even seeking the assistance of other specialist teams. The need to generate adequate data on the items listed above, in order not to have surprises in the technical aspects during the production phase cannot be over-emphasized.

Pooling of information with producers and users

Just as the production team requires certain essential information from the development teams and the users, the development team requires the following inputs from the users and the production team.

(i) Survey of the existing comparable products, their performance characteristics, quality standards, pricing and improvements desired by users. (ii) Survey of trends which may influence the onset of obsolescence of the product. (iii) Information, if any, from value engineering point of view, which may help in cost reduction without affecting performance. This could include use of alternate materials, processes, etc. (iv) Data on facilities accessible to the production team for production, inspection, performance evaluation and environment tests, so that the minimization of need for new facilities can be an objective of the development team. (v) Data on availability, quality standard, and prices of raw materials and components.

Management support

Any activity involving teams, organizations, funds and schedule needs management support. Individual and common responsibilities of the participating persons and organizations are to be spelled out in detail. Periodic reviews are to be carried out at the different managerial levels concerning technical, financial and schedule-related matters. For the sake of brevity, these are not elaborated here. However, the most critical factor concerning the attitude of all those who are responsible for implementing and reviewing the activities needs to be discussed here. A memorandum of understanding (MOU) between the participating organizations is generally entered into covering the various aspects of technical, financial and schedule-related matters. The MOU is a charter for

actions under foreseeable conditions. However, when unforeseen situations arise, the MOU has always to be supplemented by the will and determination to succeed. This may call for amendments, to the MOU placing varying additional burdens on the participants. Further, the participating teams should be made to feel that the product is the outcome of their joint efforts rather than that of the development team alone. The knowledge and experience base of both the development and the production teams needs to be used in bringing out the product. Admittedly, the development team may have an edge over the production team in areas of design, technology, craftsmanship skills and performance evaluation. Likewise, the production team may have an edge over the development team in areas of production processes and equipments, sources of materials and components, costs involved in achieving quality standards, economizing on materials and energy consumption.

Technology upgradation

It is clear that passing on a product for production entails design and technology freeze. Does it mean that in this scheme of things there is no scope for improvement of design, and technology upgradation and that the innovation process is given up once the user's requirements are apparently met? Fortunately, the innovation process is continued relentlessly. However, the utilization of innovation is carried out in a qualitatively different manner. In this context, it is useful to recognize that innovation process results in a monotonic rise with time in the values of parameters representing performance, quality and productivity. The rate of rise may vary depending on achievement of major or minor breakthroughs during the innovation process. The design and technology freeze, implying the keeping of the product parameters at a fixed level, results in growth of gaps between the realizable and the frozen values of the product parameters. Upgradation of the design and technology cannot be carried out as and when the development team accomplishes them, but is carried out subsequently when the cost of implementing the upgradation is justified by the benefits of the improved product. Thus the upgradation adopted in production is like climbing up a step. This process may be repeated over a period. From the above, it is recognizable that while the product parameters undergo a continuous ramp-like growth due to innovation, they are adopted in a staircase-like manner in the production process. Over a long term the parametric levels in the innovation and production processes are nearly the same, however, at any point in time the parameters adopted for production may in general be inferior to those achieved in innovation.

Periodic quality audit

Once the production process is stabilized and the sources and quality parameters of inputs, raw materials and bought out parts are standardized, the product quality is well assured. However, small and slow changes may occur in the production process and the parameters of inputs due to a number of reasons, such as, wear of production equipment, drift in calibration of crucial measuring instruments, turn-over of critical personnel and change of suppliers of inputs. Such imperceptible changes can seriously affect the quality and yield of the product. A periodic quality audit addressing the above-mentioned parameters is therefore essential in order to maintain trouble-free production.

Some unusual aspects

The above mentioned list of items on which data has to be generated for undertaking production is fairly obvious. However, such issues as dispersal of the production process to more than one institution in order to utilize facilities wherever they may exist and thus minimize setting up of new facilities may not surface usually. In the production of advanced technology products, generally requiring large capital outlays, this issue is of major concern. If significantly expensive new facilities are essential, additional capital costs and facilities-build-up time will greatly influence the production costs and time to take the product to users. On the other hand, if the entire production process is not under one roof, smooth flow of production would require well-conceived coordination between the participating facilities. This can add to the uncertainties regarding the uninterrupted availability of the product to the users. A trade-off study to determine how much should be under one roof and rest can be dispersed may be necessary. The trade-off study may also suggest progressive variation of the dispersal management.

Indirect benefits to a production agency of undertaking production of advanced technology products with stringent quality assurance norms are not commonly recognized, although a little reflection should make the benefits obvious. The following brings out the benefits. Some examples of the quality assurance requirements peculiar to advanced technology product are:

- (i) The production process is divided into a suitable number of stages and in-process stage inspection is carried out preferably by the process operators themselves. This is in contrast to the usual practice of inspection by an inspection team only at the end of the production process. Under the modified procedure, the production process is allowed to continue without interruption only if the results of stage inspections are

satisfactory. Failure in stage inspection, however, calls for rework or rejection, thus avoiding infructuous processing effort and possible waste of material. This also increases the involvement and dedication of the process operators to the achievement of quality; (ii) On-line recording and analysis of production processes and inspection activities are given in ref. 2. These bring out (a) whether the production process wandered outside the specified tolerances at any stage, (b) what rework was carried out, if any, and (c) whether any performance parameters of the product are outside the specified limit.

A review of the above quality assurance data permits confident decision on the suitability of the product for the intended service by exacting users. This data also provides traceability to be able to correlate failure of the product during service with lapses, if any, during the design and production processes. Beneficial influence of such quality assurance practices on the production yield and product quality enhances the image of the production agency.

Successful production of a newly developed product has another significant, though intangible, benefit. It is the growth of mutual confidence between the development and production teams to be able to undertake challenging development and production tasks. Likewise, the user community begins to rely on such products and expects more of such successful collaborations.

Selection of production agency

The production agency plays the critical role of implementing the know-how to produce and market the new goods and services with the human and infrastructural resources accessible to them. Easy access to the needed skilled manpower and facilities for production, quality control and test and evaluation are the minimum prerequisites of a suitable production agency. If the new products and services are in line with the existing products and services of the prospective production agency, the task of successful production and marketing becomes simpler. If the production agency also has the motivation and internal capability of further value addition to the know-how, it becomes an excellent additional qualification for the selection of the production agency. An open meeting with the prospective production agencies, in which the various features of the know-how are presented by the R&D team and the capabilities of the production teams are discussed individually, can prove to be a speedy step in the selection process. Exchange of visits to the R&D laboratories and production facilities is another useful step in the selection process. Ready agreement on sharing of responsibilities during the technology transfer, implementation and marketing activities creates proper conditions for successful production.

Case histories

The concepts of linking technology development with production have been used extensively in the Indian Space Research Organization (ISRO) in general and the Vikram Sarabhai Space Centre (VSSC), in particular. Four case histories are cited here for illustration. These are concerning production of: (i) Miniature rate gyroscope; (ii) Electronics assemblies; (iii) Carbon cloth and (iv) Telemetry systems representing different fields. There are other numerous examples linking development with production in the fields of alloys, polymers, liquid fuels, large variety of mechanical components and assemblies and software which are not discussed in this paper for the sake of brevity and as the selected case histories discussed in some detail illustrate the concepts sufficiently.

Miniature rate gyroscope

VSSC had developed a highly sophisticated electro-mechanical instrument for measuring the speed of rotation of solid bodies, undergoing complex motion, and producing a proportional electrical signal with stringently specified precision and accuracy. The instrument, operating on the principle of conservation of angular momentum and interaction of gyroscopic torques, is known as a rate gyroscope. The main sub-assemblies comprising the gyroscope are a spin motor usually running at 24000 rpm, a torsion bar, a microsyn, a flotation system and a pivot-jewel assembly. The sub-assemblies have a total of 16 high precision fabricated parts and a number of bought-out parts. The physical size of the instrument puts it in the miniature category.

During the development phase, the VSSC team evolved the geometry and the material for the parts, the processes for machining, fabrication and heat treatment, the assembly procedures and performance checks on the sub-assemblies, the process tools required during the production and assembly and procedure for assembly and performance evaluation. The development team also evolved the detailed quality assurance procedures concerning raw materials, bought-out parts and production and assembly process. After achieving the required performance of the gyroscope consistently over a number of units, the design, fabrication, assembly, performance evaluation and quality assurance information, as listed earlier, was documented as a Technology Transfer Document. Then, the search for a suitable production agency was made. A facility which was producing instruments based on comparable technologies under licence from a number of foreign manufacturers was located. After discussing with the production facility and agreeing on the terms of the order and the minimum significant size of the order, a two-phase production order was placed

with provision for total buy-back. In the first phase, only the full sets of the 16 fabricated parts were to be produced. In the second phase, which was to commence only after completing successfully the first phase, the complete instrument was to be produced. In order to reduce the uncertainties on schedule, quality and cost all special raw materials and bought-out parts were supplied by VSSC.

When the production agency commenced the fabrication of parts, difficulties were experienced in realizing the stringent geometrical tolerances on some of the parts. Difficulties were also experienced in achieving quality standards in soldering electrical connections, miniature coil winding and inspection of precision engineered parts. Some difficulties also arose because the production agency was following the method of doing inspection at the completion of the fabrication and machine shop work. Stage inspection was not in vogue. Because of this practice, the shop floor technicians were not issued the precision gauges needed for stage inspection. As a result, the non-conformance with the specified geometrical tolerances was detected only at the completion of the fabrication and machine shop work. Consequently, the yield was poor for even those parts which the production agency could manage to produce in the early trials. In the management level review, these difficulties were brought up and the following remedial action were identified for implementation:

(i) Training-cum-demonstration of fabrication, machining, soldering, miniature coil winding and stage inspection of the difficult-to-produce parts to the technicians, inspectors and supervisors of the production facility at the development laboratory. If necessary, repeat the demonstration of producibility at the production agency using facilities available there by the development laboratory technicians. (ii) Introduction of stage inspection at the production agency, entailing increase in the scope of responsibility of the production technicians and for this purpose equipping them with the required precision gauges.

During the subsequent management level reviews, while significant improvement in the yield of most of the parts was observed, as a result of the above mentioned measures, a few parts continued to elude satisfactory production. In order to solve this problem and to improve the yield further, the production agency decided to set up a separate Cell in the facility to fabricate and machine the gyro parts and to equip the Cell with a few special machine tools recommended by the VSSC development team. On registering satisfactory progress on the first phase, the second phase was taken up concurrently with the first phase, as a modification of the earlier plan.

The gyroscopes coming from this production arrangement have been available to the entire launch vehicle

programme of ISRO from SLV-3, ASLV to PSLV and have never been cause of the failure of the launch vehicle missions. All through the working together, the development and production teams maintained the spirit of searching for solutions rather than alibis for failures and of strict adherence to systematic quality assurance procedures.

Electronics assemblies

The space launch vehicles and satellites have on-board a large number of special electronics assemblies for performing the functions of measurement, signal processing, data acquisition, telemetry, trajectography, telecommand, attitude control, electric power conditioning, flight sequencing, etc. These assemblies span the frequency spectrum from d.c. to several Gigahertz and are of both analog and digital type. The electronics components used in them are of high reliability standard and the workmanship standards on components preparation, mounting, soldering, harness preparation are of equally high reliability standard, so that the assembly can successfully withstand the hostile environment during launch and in-orbit operation in space. The quality and workmanship standards are given in refs 3-7. For the assemblies to deliver performance in a narrow tolerance band in terms of gain, frequency and voltage stability, over a wide temperature environment, the component values need to be in correspondingly specified narrow bands. Tuning, performance checking and quality inspection at various stages of the production are in general indispensable, in order to get satisfactory yield from the production.

After the satisfactory completion of the design and development process at VSSC, production documents were prepared incorporating the information listed earlier in this paper. A number of suitable production agencies were identified and contracted with the production of the electronics assemblies used in the ASLV, PSLV and the Rohini Sounding Rockets. Although the technicians, inspectors and supervisors at the production agencies were reasonably well skilled, it was found necessary to give them additional training in the techniques of making high reliability electrical connections, spotting sub-standard connections and repairing the sub-standard connections while maintaining the quality standards. It was also found necessary to introduce stage inspection during the production of printed circuit boards and the final assembly operations.

During the periodic management level reviews, the spirit of problem solving in order to achieve the goals was maintained by the development and production teams.

Currently, about 38 varieties of electronics assemblies, ranging from the simple signal conditioning units to complex guidance and control computers, are being produced in industry. The electronics assemblies so

produced have given faultless performance in the ASLV, PSLV and RSR flights. A few of these electronics sub-assemblies are also used completely satisfactorily in the IRS-1A, 1B, 1C and INSAT-2A, 2B, 2C satellites providing in-orbit services.

Carbon cloth

The nozzle of the solid propellant rocket motors is lined with layers of phenolic-resin impregnated carbon cloth. The basic function of these layers is to maintain the internal dimensions and the strength of the metallic structures of the nozzles under supersonic gaseous flow at temperature higher than 2000°C and the flow lasting up to two minutes. The carbon cloth is produced by carbonizing a special grade of rayon cloth, having a particular type of weave pattern. The carbonization is a multi-stage process and is to be carried out in furnaces with special liquid medium and gaseous environment and at different temperatures going up to about 1000°C. The carbon cloth is about 1 m wide and in continuous lengths of not less than 50 m. Specifications of the cloth in respect of carbon and sodium contents, breakstrength in warp and fill directions, thickness and mass per unit area have stringent tolerances. There are only a handful of qualified producers in the whole world of this grade of the carbon cloth and the technology of production is a closely guarded commercial and strategic secret.

VSSC had developed *de novo* the carbon cloth production process in 40 mm width and 500 mm length size and prepared a detailed document giving the desired rayon cloth characteristics, the carbonization process and quality control procedures. The production agency, identified through a competitive selection process, was to scale up the carbonization process and adopt a batch or continuous process to produce the carbon cloth with the specified characteristics. The selected production agency turned out to be a brand new venture, entailing the *de novo* design and procurement of the process equipments and design and construction of the plant buildings. VSSC organized for them a technology demonstration programme in order to (i) confirm the reproducibility of the lab scale carbon cloth processing technology, (ii) familiarize with the processing testing and evaluation techniques, and (iii) enable them to have an independent verification of the technologies under transfer. During the selection of the process equipments and the scaling up exercises the development team provided specialist advice. The initial technical difficulties faced in commissioning the process equipments, evolving the scaled up process, analysis of cloth samples, improving the yield were painstakingly reviewed and overcome. The production agency also came up with some useful innovative ideas. The carbon cloth is now

being produced regularly, fully conforming to the specified quality standards and used in the solid propellant rocket motors of VSSC.

Telemetry systems

ISRO had developed a complete set of telemetry system for monitoring the inflight performance of sounding rockets and satellite launch vehicles and the in-orbit health parameters of satellites. Both the on-board and ground segments and both analog and digital versions were developed and used extensively in over hundred missions of Rohini Sounding Rockets, SLV-3 vehicle, ARYABHATA and BHASKARA satellites. The performance of the telemetry system was invariably spot-less and helped ISRO extract valuable information from these missions. On the basis of this performance record a specially configured telemetry system was designed, built and supplied to Hindustan Aeronautics Ltd for use in their new aircraft developments. Encouraged by these achievements, ISRO tried to interest Indian industry to undertake production of the telemetry system for application to the massive oil and gas pipeline projects in the country. A workshop on Application of Telemetry in Industry was held followed by an ISRO-industry meet on the theme. In spite of the proper credentials of ISRO and strenuous efforts to familiarize industry with the capabilities and the potential market for the telemetry system, imported know-how won the pipeline application. Apprehending similar preference in other applications, industry did not select the know-how from ISRO. Thus, this constitutes a case of unsuccessful production for non-space applications.

ACKNOWLEDGEMENTS. The concepts reported here were evolved at VSSC with the participation of a large number of engineering and technical staff. As such it is not practical to acknowledge the contribution of individuals. Extremely useful suggestions to improve the contents of this paper by Prof. S. Dhawan, Member, Space Commission, Shri N. Sampath, Executive Director, ANTRIX Corporation Limited, Shri N. Sivasubramanian, Shri K. J. Janardhana Rao and Shri M. C. Mittal of VSSC are gratefully acknowledged.

Viral cell recognition and entry

Michael G. Rossmann

Department of Biological Sciences, Purdue University, West Lafayette, Indiana 47907-1392, USA

Rhinovirus infection is initiated by the recognition of a specific cell surface receptor. The major group of rhinovirus serotypes attach to intercellular adhesion molecule-1 (ICAM-1). The attachment process initiates a series of conformational changes resulting in the loss of genomic RNA from the virion. X-ray crystallography and sequence comparison suggested that a deep crevice or canyon is the site on the virus recognized by the cellular receptor molecule. This has now been verified by electron microscopy of human rhinovirus 14 (HRV14) and HRV16 complexed with a soluble component of ICAM-1.

A hydrophobic pocket underneath the canyon is the site of binding of various hydrophobic drug compounds which can inhibit attachment and uncoating. This pocket is also associated with an unidentified, possibly cellular in origin, 'pocket factor'. The pocket factor binding site overlaps the binding site of the receptor. It is suggested that competition between the pocket factor and receptor regulates the conformational changes required for the initiation of the entry of the genomic RNA into the cell.

Viral receptors

Unlike plant viruses, most animal, insect and bacterial viruses attach to specific cellular receptors that, in part, determine host range and tissue tropism. Viruses have adapted themselves to utilize a wide variety of cell-surface molecules as their receptors, including proteins, carbohydrates and glycolipids. Some viruses recognize very specific molecules (e.g. a large group of rhinoviruses recognize intercellular adhesion molecule-1 (ICAM-1)), while other viruses recognize widely distributed chemical groups (e.g. influenza viruses recognize sialic acid moieties). The tissue distribution of the receptor will in part determine the tropism of the virus and, hence, the symptoms of the infection. Similarly, species differences between receptor molecules can limit host range. For instance, only humans and apes have been shown to be susceptible to rhinovirus infections, a property correlated to the inability of human rhinoviruses to bind to the receptor ICAM-1 molecule in other species.

Although there are extensive similarities of sequence, structure and physical properties among picornaviruses which show that these viruses have evolved from a common ancestor¹⁻³, nevertheless they recognize a variety of receptors (Table 1). Possibly the primordial virus had

the ability to weakly bind to a large number of different molecules. With time, different viruses evolved which became progressively more efficient and specialized towards recognizing one particular molecule as a way of infecting specific cells. Indeed, the grouping of viruses might suggest such a scenario. Thus, all polioviruses appear to recognize the same receptor and most coxsackie A viruses recognize their own receptor, while coxsackie B viruses recognize yet another receptor. Therefore, it is surprising that rhinovirus serotypes can be divided into three groups which recognize different receptors^{4,5}. Furthermore, the receptor for the major group of rhinoviruses, ICAM-1, belongs to the immunoglobulin superfamily^{6,7}, whereas the receptor for the minor group has been reported to be the low density lipoprotein (LDL) receptor⁸.

Receptor binding is only the first, albeit essential, step in the infection process. The virus, or the virus genome alone, then has to enter the cell, a process which requires translocation of the viral genome or a sub-viral particle across the membrane into the cytoplasm, and, in some cases, into the nucleus. Since delivery of the viral genome into the cell involves major rearrangements of the capsid structure, entry must be a tightly regulated process which is triggered by the cell. The mechanism of entry can be, in the case of enveloped viruses, by fusion of the viral envelope with the limiting cellular membrane (Figure 1). This process has been well characterized in several viruses (Semliki Forest virus (SFV), influenza virus, Sendai virus) where fusion is induced by specific viral envelope proteins, activated by conformational changes induced by the low pH environment of endosomes. The mechanism by which protein-encapsidated viruses like picornaviruses³ enter the cytoplasm has not been well elucidated, but must differ significantly in detail from the membrane-fusion strategy demonstrated by enveloped viruses in that RNA must be translocated through the membrane.

Rhinovirus structure and the canyon hypothesis

The genus *Rhinovirus* is composed of a group of over 100 serologically distinct viruses, which are a major cause of the common cold in humans³. These viruses belong to the picornavirus family, which also contains the genera *Enterovirus*, *Aphthovirus*, *Cardiovirus* and

REVIEW ARTICLES

Table 1. Receptors families for picornaviruses based on virus competition for cell receptors

Virus	Receptor molecule	Receptor family	Reference
Human rhinovirus major group: 78 serotypes, including 3, 5, 9, 12, 14, 15, 22, 32, 36, 39, 41, 51, 58, 59, 60, 66, 67, 89	ICAM-1	Ig (5 Ig domains)	Abraham and Colonno ⁴ , Greve <i>et al.</i> ⁶ , Staunton <i>et al.</i> ⁷
Human rhinovirus minor group: 11 serotypes, including 1A, 2, 44, 49	Low-density lipoprotein (LDL) receptor	LDLR	Abraham and Colonno ⁴ , Hofer <i>et al.</i> ⁸

Figure 1. One possible endocytotic process (adapted from Rawn¹⁰³). Note, however, that in most cases it is not known when and where the receptor and virus part company, whether it is necessary for the virus to be bound to the receptor during uncoating and what is the mechanism by which RNA translocates the membrane.

Hepatitis A virus. The picornaviruses are small, icosahedral, nonenveloped, single-stranded RNA viruses. X-ray crystal structures have been determined for at least one member in each picornavirus genus except for hepatitis A viruses^{1,9-13}. Polioviruses (genus *Enterovirus*) are structurally the most similar to rhinoviruses. Unlike the enteroviruses, rhinoviruses are unstable below pH 6. The infectious virion has a molecular weight of about 8.5×10^6 daltons and an external diameter of around 300 Å.

Each of the 60 icosahedral protomers in picornaviruses contains four viral polypeptides, VP1-VP4. VP1, VP2 and VP3 reside on the exterior of the virus and make up its protein shell (Figure 2). These three peptides, each having a molecular weight of roughly 35 kDa, contain a common eight-stranded, antiparallel, β -barrel motif¹ (Figure 3, Table 2). Their amino termini intertwine to form a network on the interior of the protein shell. Five VP3 amino termini form a five-stranded helical β -cylinder on the virion's interior about each icosahedral five-fold axis. This β -cylinder stabilizes the pentamer and is thought to be important for its assembly^{9,14}.

VP4 is smaller than the other viral polypeptides and resides inside the virion's protein shell. VP4 is lost from the capsid as a result of virus uncoating, although the specific role of VP4 in uncoating or entry has not been elucidated. A mutant of human rhinovirus serotype 14 (HRV14) defective in VP4-VP2 cleavage¹⁵ is able to bind to receptor and undergo cell-induced conformational transitions but is unable to initiate a new round of replication, suggesting that cleavage of VP0 into VP2

and VP4 (cf. refs 10, 14) is an essential prerequisite for successful cell infection. The amino terminus of VP4 is myristylated, which may promote its association with lipid membranes during viral assembly or uncoating¹⁶. In poliovirus, the myristylate moiety lies inside the virion coat close to the β -cylinder. The first 25 to 28 amino-terminal residues of VP4 are mostly disordered in rhinovirus structures, but density consistent with myristylate is seen internally near the center of the pentamer in rhinoviruses 14, 1A and 16 (refs 13, 17, 18).

Each of the three larger capsid proteins has various insertions between the β -strands of the basic folding motif. Many of these insertions decorate the viral exterior and form 'puffs' and loops which are hypervariable and have been shown to be the binding site of neutralizing antibodies^{1,19,20}. The surfaces of rhinoviruses (and polioviruses) contain a series of remarkably deep crevices or 'canyons' (Figure 2), unlike anything observed in plant virus structures. The canyon is formed roughly at the junction of VP1 (forming the 'north' rim) with VP2 and VP3 (forming the 'south' rim). The GH loop in VP1 (often referred to as the 'FMDV loop' because of its immunodominance in the homologous foot-and-mouth disease virus (FMDV) structure) forms much of the floor of the canyon. Together with the carboxy termini of VP1 and VP3, the GH loop of VP1 also participates in the formation of the 'south' rim of the canyon.

It was hypothesized¹ that the canyon (one around each five-fold vertex; Figure 2) in HRV was the site of receptor attachment, largely inaccessible to the broad antigen-binding region seen on antibodies. Thus, residues

Figure 2. Top left: Diagrammatic view of picornavirus showing VP1, VP2 and VP3 and the deep cleft or 'canyon' running around each five-fold vertex. The 6S protomeric assembly unit (which differs from the geometric definition of the asymmetric unit) is shown in heavy outline on the icosahedron. Center: Enlargement of one icosahedral asymmetric unit showing the outline of the canyon and the entrance to the VP4 pocket. in the lining of the canyon, which should be resistant to accepting mutations that might inhibit receptor attachment, would avoid presenting an unchanging target to neutralizing antibodies. Indeed, the neutralizing immunogenic sites that had been mapped by escape mutations were not in the canyon, but on the most exposed and variable parts of the virion both in HRV^{1,19,20} and in poliovirus^{9,21}. The 'canyon hypothesis' suggests that one strategy for viruses to escape the host's immune surveillance is to protect the receptor attachment site in a surface depression (Figure 4). Similar depressions related to host cell attachment have also been found on the surface of the haemagglutinin spike of influenza virus^{22,23}, tick-borne encephalitis virus (Harrison *et al.*, private communication) and may be the case for human immunodeficiency virus²⁴.

Binding of ICAM-1, the major group rhinovirus receptor, to virus surface

There are at least 78 serotypes²⁵ that bind to ICAM-1, the major group rhinovirus receptor^{6,7}. The ICAM-1 molecule has five immunoglobulin-like domains (D1–D5,

numbered sequentially from the amino end), a transmembrane portion and a small cytoplasmic domain^{26,27}. Domains D2, D3 and D4 are glycosylated (Figure 5). Unlike immunoglobulins, ICAM-1 appears to be monomeric⁷. Mutational analysis of ICAM-1 has shown that domain D1 contains the primary binding site for rhinoviruses as well as the binding site for its natural ligand, lymphocyte function-associated antigen-1 (LFA-1)^{27–30}. Other surface antigens within the immunoglobulin superfamily that are used by viruses as receptors include CD4 for human immunodeficiency virus type 1 (refs 31–34), the poliovirus receptor³⁵ and the mouse coronavirus receptor³⁶. In ICAM-1 in the poliovirus receptor^{37,38} and in CD4³⁹, the primary receptor virus binding site is domain D1. The structures of the two amino-terminal domains of CD4 have been determined to atomic resolution^{40–42}. Truncated proteins corresponding to the two amino-terminal domains of ICAM-1 (D1D2 consisting of 185 amino acid) as well as the intact extracellular portion of ICAM-1 (D1–D5 consisting of 453 amino acids) have been expressed in CHO cells⁴³. The desialated form of D1D2 has been crystallized⁴⁴.

C. Music, J. M. Greve, T. S. Baker and M. G. Rossmann, unpublished results) and of D1D5 with HRV16 (Kolatkhar *et al.*, unpublished results) has been determined using cryoelectron microscopy and image reconstruction procedures (Figure 6). The position of the ICAM-1 molecule relative to the icosahedral symmetry axes of the virus is unambiguous (Kolatkhar *et al.*, unpublished results) and shows the receptor binding into the canyon (Figure 7). Each D1D2 molecule has an approximate dumbbell

Figure 3. Schematic representation of the VP1 fold of HRV14. The folding topology of the two sheets 'BIDG' and 'CHEF' is the same in VP2 and VP3 as well as in most other viral capsid proteins. The binding site of antiviral WIN compounds within the hydrophobic interior of VP1 is also shown.

Figure 4. The presence of depressions on the picornavirus surface suggests a strategy for the evasion of immune surveillance. The dimensions of the putative receptor binding sites, the 'canyon', sterically hinder an antibody's (*top right*) recognition of residues at the base of the site, while still allowing recognition and binding by a smaller cellular receptor (*top left*). This would allow conservation of receptor specificity while at the same time permitting evolution of new serotypes by mutating residues on the viral surface, outside the canyon.

shape, consistent with the presence of two-domain structure. A difference map between the EM density and the 20 Å resolution HRV16 or HRV14 densities confirmed that the D1D2 molecule binds to the central portion of the canyon roughly as predicted by Giranda *et al.*⁴⁶. There are some small differences in orientation of D1D2 when complexed to HRV16 or HRV14 which may relate to the change in length of the VP1 BC loop forming the north rim of the canyon (Kolatkhar *et al.*, unpublished results). The D1D2 ICAM fragment is oriented roughly perpendicular to the viral surface and extends to a radius of about 205 Å. Its total length is about 75 Å.

Extensive structural similarity between D1D2 of ICAM-1 and CD4 was shown by means of a cross-rotation function between the known structure of D1D2 for CD4 (refs 40, 41), and the crystal diffraction data for ICAM-1 D1D2 (P. R. Kolatkhar and M. G. Rossmann, unpublished results). Thus, it seemed reasonable to use the known structures of CD4 for fitting the reconstructed density map (Figure 6), although there was slightly too little density for domain D1 and too much density for D2. A better assessment of the fit of domain D1 to the density was obtained by taking the predicted D1 structure of ICAM-1, including all side chains, and superimposing it onto the fitted C_α backbone of CD4. One major difference is that although domain D1 of CD4 resembles a variable, immunoglobulin-like domain with two extra β-strands, the ICAM-1 sequence is shorter and more like a constant C1 domain⁴⁶, although Berendt *et al.*⁴⁷ suggest that the topology might be like a constant C2 domain in which strand C is not part of either sheet

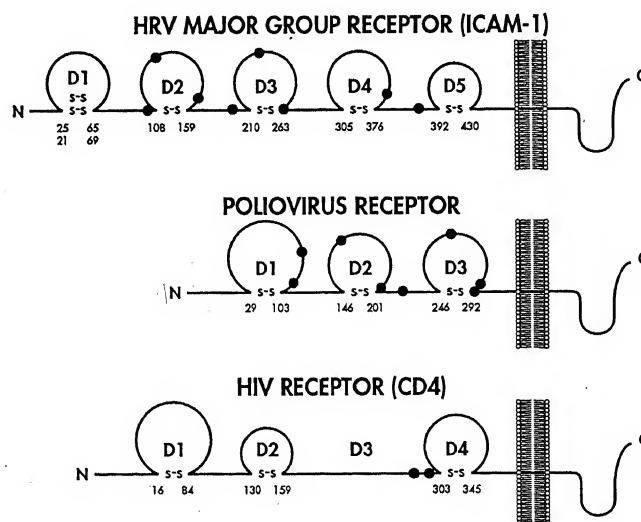

Figure 5. Schematic diagram of viral receptors. The relative size and distribution of immunoglobulin-like domains are shown. The black circles show the position of potential glycosylation sites. Numbers indicate the amino acid positions of Cys residues involved in predicted disulfide (S-S) bridges. [Reprinted with permission from Colonna¹⁰⁴. Copyright by Academic Press.]

region. This gives domain D1 of ICAM-1 a sleeker appearance, consistent with the observed difference density. The extra density in D2 (in the region farthest away from the virus) compared with domain D2 of CD4 is probably due to the four associated carbohydrate groups located in this region.

The footprint of ICAM-1 onto the HRV14 structure (Figure 8) correlates very well with Colonno's mutational studies of residues in the canyon which alter affinity of the virus to HeLa cell membranes⁴⁸. All the residues are part of the canyon floor and lie centrally within the footprint of the D1D2 molecule binding site. Similarly, there is excellent agreement between the ICAM-1 footprint and residues on the virus surface whose conformation is changed by antiviral agents⁴⁹⁻⁵¹.

Figure 6. Stereo views of cryo EM image reconstructions of (A) HRV16 (green)–D1D2 (orange) and (B) HRV14 (blue)–D1D2 (orange) complex, viewed along an icosahedral two-fold axis in approximately the same orientation as in Figure 2. Both (A) and (B) show sixty D1D2 molecules bound to symmetry-equivalent positions in the canyons on the virion surface. (C) Shaded-surface view of HRV14 (blue), computed from the known atomic structure¹, truncated to 20 Å resolution.

Virus entry and uncoating

Productive viral uncoating requires that the RNA moves from inside the viral protein shell, through a cellular membrane, into the cytosol. Such displacement probably requires large conformational changes in the rhinovirus coat. For poliovirus or rhinovirus, acidification of endosomes, may be required for an infection to proceed normally as measured by either progeny virus production or cytopathic effects⁵²⁻⁵⁶.

Rhinovirus and poliovirus 149S infectious virions undergo several progressive transformations^{57,58} when bound to cells, which can be followed by sedimentation through sucrose gradients. The 149S virions are initially converted to 135 to 125S particles which have lost VP4 but retain RNA ('A-particles'). Subsequently, the RNA is released with the formation of 80S empty capsids as well as small capsid fragments.

The A-particles have a number of properties which suggest a role in virus entry. They have been shown to be hydrophobic and able to bind to liposomes^{59,60}. It has also been shown that the formation of poliovirus A-particles is associated with externalization of the N-terminus of VP1 and that removal of approximately 30 residues from the N-terminus of VP1 by proteolysis abolishes the ability of poliovirus to bind to liposomes⁶¹.

Figure 7. Structure of HRV16 VP1 (blue), VP2 (green) and part of VP3 (red) complexed with D1D2 of ICAM-1 (orange) modeled from the known structure of CD4.

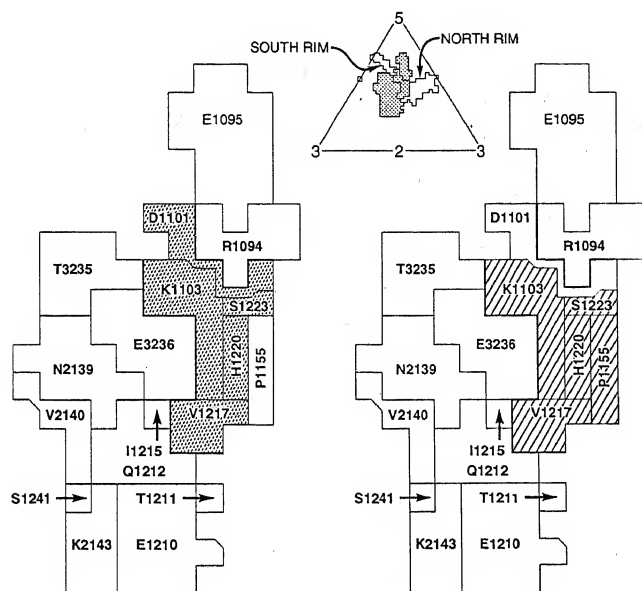

Figure 8. (Top) View of the icosahedral asymmetric unit bounded by adjacent five- and three-fold axes, outlining residues on the HRV14 surface. The limits of the canyon are shown, arbitrarily demarcated by a 138 Å radial distance from the viral center¹⁰⁵. Residues under the ICAM-1 footprint are stippled. Improved resolution of the electron density could only marginally alter the HRV residues at the virus-receptor interface. (Left and right) Enlarged view of the residues in the ICAM-1 footprint showing the residues (hatched areas) that, when mutated, affect viral attachment (right)⁴⁸, and the residues (stippled areas) altered in structure by the binding of antiviral compounds that inhibit attachment and uncoating (left)⁴⁹. [Reprinted with permission from Olson *et al.*⁴⁵. Copyright by the National Academy of Sciences.]

The sequence of the amino-terminal 23 residues of VP1 suggests that it could form an amphipathic α -helix and, thus, could promote interactions with lipid bilayers.

A-like particles can be generated under certain conditions *in vitro*^{60,62,63}. HRV14 incubated at pH 5–6, the pH likely to be found in endosomes, is converted to 135S A-particles. HRV14 incubated with soluble ICAM-1 is converted, through a virus-receptor complex intermediate, to 80S empty capsids, suggesting that receptor binding can destabilize the virion⁶⁰.

Since the conformational changes required for uncoating which occur on acidification are probably similar to those that occur on viral interaction with receptor, a structural determination of these changes could be useful. It has been possible to study the initial changes that occur in wild-type HRV14 crystals upon lowering the pH by using a very high intensity synchrotron X-ray source⁶⁴. This permitted the rapid recording of the diffraction pattern before the crystals completely disintegrated. It was found that an ion-binding site (Figure 9) on the icosahedral five-fold axes, the interior of the virus shell near the five-fold axes including the amino end of VP3, much of the ordered part of VP4 and the GH loop of VP1 all became disordered. Furthermore, the magnitude of the disorder increased as the time of acid exposure increased. The expansion of the β -cylinder and cation release, therefore, may be among the first events permitting eventual escape of VP4s, possibly along the five-fold axial channels. There are parallels to this process in the externalization of VP1 through

Figure 9. A putative Ca site in HRV16 with five His 1134 ligands (Hadfield *et al.*, unpublished results). Similar cation sites are found in CVB3 and HRV14. The ion comes off on acidification in HRV14.

the five-fold axial channels of canine parvovirus⁶⁵, and the ejection of single-stranded DNA through the five-fold ion channel of ϕ X 174 (refs 66, 67). An alternative proposal made by Fricks and Hogle⁶¹ based on mutational analyses and a comparison with properties of tomato bushy stunt virus⁶⁸ suggests that the first step in uncoating and the externalization of VP1 is a weakening of the contacts between protomeric units (Figure 2).

Inhibition of uncoating and the pocket factor

Capsid-binding, antiviral agents such as the 'WIN' compounds bind into a hydrophobic pocket in VP1 below the canyon floor. Not only do they inhibit attachment in HRV14 and other major group rhinoviruses, but they

also stabilize major and minor group rhinoviruses *in vitro* to acidification⁶⁹ and heat⁷⁰. HRV14 differs from other picornaviruses in that its pocket is empty in the native structure. For example, there is electron density in the homologous pockets of poliovirus Mahoney 1, poliovirus Sabin 3 and in a chimera of poliovirus 2 (refs 9, 12, 71). This density has been interpreted as a sphingosine or palmitate-like molecule because of the hydrophobic nature of the pocket and the polar environment at one end of the pocket. Similarly, the somewhat smaller electron density in the pocket of HRV1A (refs 13, 72) and HRV16 (ref. 18) has been tentatively interpreted as a fatty acid, eight or more carbon atoms long. A rather longer 'pocket factor' is found in this pocket for coxsackievirus B3 (CVB3) (J. K. Muckelbauer,

Figure 10. Electron density in the hydrophobic interior of VP1 corresponding to the site of binding of certain antiviral compounds (Figure 2) of coxsackievirus B3 (Muckelbauer *et al.*, unpublished results).

L. Tong, M. G. Rossmann and M. J. Kremer, unpublished results) (Figure 10). While it is possible that the pocket factor might be a small impurity picked up in the extraction procedure, with detergent or during crystallization with polyethylene glycol, these conditions differ greatly among the known structures. Smith *et al.*⁴⁹ imply, while Filman *et al.*¹² explicitly propose that the pocket factor could be cellular in origin and might regulate viral assembly and uncoating.

Binding of WIN compounds to HRV14 causes major conformational changes in the pocket and, hence, also in the canyon floor (the receptor attachment site). These changes were correlated to inhibition of attachment in the presence of the antiviral compounds^{50,51}. In contrast, in HRV1A (a minor receptor group virus) and polioviruses, where the WIN compounds merely displace the pocket factor without a correspondingly large conformational change, there is inhibition of uncoating but not of attachment. Preliminary results suggested that rhinoviruses of the minor receptor group exhibited no inhibition of attachment, whereas those of the major receptor group behaved like HRV14 for which attachment is inhibited.

Figure 11. Schematic representation of the binding of the antiviral agents WIN 51711 and 52084 into a pocket underneath the canyon in HRV14. This causes enlargement of the pocket and conformational changes in the floor of the canyon, inhibiting attachment of the virus to HeLa cells in some cases, and also increasing the stability of the virus in all cases. [Reprinted with permission from Dutko *et al.*¹⁰⁶. Copyright by Springer-Verlag, New York.]

Thus, it was a surprise to find 'pocket factor' electron density in HRV16, causing the shape of the pocket to resemble that of the 'WIN filled' form of HRV14 (refs 13, 72).

In HRV1A and HRV16, the more active antiviral compounds tend to have an aliphatic chain less than or equal to five carbon atoms long⁷³, correlating with the available space within the binding pocket^{72,74,75}. In HRV14, the most active antiviral agents tend to be longer with seven-carbon aliphatic chains. For example, WIN 56291 has an aliphatic chain of only three carbons (compare Figure 11) and is equally active against HRV16 and HRV1A, but less active against HRV14. Thus, for each serotype there is an optimal drug size which displays the greatest activity and binding affinity^{74,75} and

Figure 12. Conditions for inhibition of viral attachment by WIN compounds. Crystallographically and electron microscopically determined structures are in yellow and pink, respectively, while hypothetical structures are in gray. (Top) In wild-type HRV14, the pocket factor binds weakly and is not observed in crystallographic studies. When WIN compounds bind into the pocket, they deform the roof of the pocket which is also the floor of the canyon. This inhibits the attachment of the virus to the ICAM-1 receptor and, hence, presumably the binding affinity of WIN is greater than that of ICAM-1. When ICAM-1 recognizes the canyon floor, the putative pocket factor must be displayed by ICAM-1 and, hence, the binding affinity of ICAM-1 is greater than that of pocket factor. (Center) Drug-resistant compensation mutants of HRV14 cluster around the canyon walls and floor (•) and increase the affinity of ICAM-1 for the virus. Although WIN compounds can bind to the virus, they do not inhibit infectivity. Thus, the binding affinity of the mutant virus to ICAM-1 is greater than that of WIN. (Bottom) Wildtype HRV16 contains a pocket factor. This can be replaced by WIN compounds which inhibit attachment. Hence, in this case the affinity of HRV16 for WIN is greater than that of ICAM-1 which is greater than that of pocket factor.

best fills the volume of the pocket. It follows that the smaller pocket factors, which can be easily displaced by WIN compounds in HRV16 and HRV1A (refs 18, 72), bind with less affinity than the antiviral compounds. Nevertheless, the pocket factors seen in the electron densities remain in the pocket even after extensive dialysis of the virus sample. The WIN compounds have a binding constant comparable to their minimal inhibitory concentrations of $\sim 10^{-8}$ M (refs 70, 76).

The role of the pocket factor

When the antiviral binding pocket in HRV14 is filled with WIN compounds or fragments of WIN compounds that do not inhibit infectivity, there is an increase in the thermal stability of the virus^{77,78}, presumably as a consequence of placing a hydrophobic molecule into an internal hydrophobic cavity^{79,80}. Similarly, drug-dependent mutants of poliovirus require WIN compounds to maintain their stability⁸¹. The pocket factor may, therefore, be required to stabilize the virus in transit from one cell to another. However, the delivery of the infectious RNA into the cytoplasm must require a destabilizing step which might be effected by expulsion of the pocket factor during the receptor-mediated uncoating.

Since ICAM-1 binds to HRV14 and to HRV16 (Figure 12), the shape of the canyon for HRV16 should be similar to that in HRV14 when ICAM-1 binding occurs. As soluble ICAM-1 binds to purified HRV14, which does not contain any pocket factor, presumably the pocket is empty when ICAM-1 binds to HRV16. However, the structure of HRV16 shows the presence of a pocket factor in the purified virus¹⁸. Hence, it must be assumed that the pocket factor is displaced before the receptor can seat itself into the canyon. In essence, there are two competing equilibria: the binding of ICAM-1 and the binding of the pocket factor to the virus. Although the sites of binding of ICAM-1 and of the pocket factor are not the same, they are in close proximity and interfere with each other. The floor of the canyon is also the roof of the pocket for the pocket factor or WIN compounds. When ICAM-1 binds, the floor is depressed downwards, which is possible only when there is nothing in the pocket. Conversely, when there is a compound in the pocket, its roof is raised upwards. The displacement of the pocket factor *per se* does not cause the virus to fall apart. For instance, when HRV14 is crystallized it does not contain a pocket factor, and the complex of HRV16 with ICAM-1 is reasonably stable. Nevertheless, the absence of pocket factor increases the potential for disruption by lowered pH or by formation of the receptor-virus complex.

Presumably, the destabilization of the virus on cell attachment is made possible by the displacement of a sufficient number of pocket factors when the receptor

competes for the overlapping binding site. Progressive recruitment of receptors is then sufficient to trigger release of the VP4s. The terminal myristate moieties of VP4 and the exposure of the amino terminus of VP1 will permit entry through the cell membrane, possibly by creating a channel along the five-fold axes of the virus⁶⁴.

A class of HRV14 drug-resistant (compensation) mutants can be selected by growing the virus in the presence of antiviral WIN compounds. Such mutants occur at a frequency of about one per 10^4 virions. They have been shown to be mostly single mutations^{77,82} and six of the seven characterized to date are situated near the walls and floor of the canyon. WIN compounds bind into the pocket of these mutant viruses and deform the canyon floor in a similar manner to their effect on wild-type viruses (M. A. Oliveira, I. Minor, R. R. Rueckert and M. G. Rossmann, unpublished data). In some of these mutants, the affinity of ICAM-1 for the virus is enhanced (R. R. Rueckert, private communication; M. P. Fox, D. C. Pevear and F. J. Dutko, unpublished data). Thus, it is reasonable to conclude that ICAM-1 binds better to these mutant viruses than the WIN compounds (Figure 12, center).

Conclusions

The canyon hypothesis, which suggested that the receptor binding site can be hidden from immune surveillance in a 'canyon' on the surface of the capsid, has been verified for the major group of rhinoviruses. Mutational analyses have indicated that the canyon is also the receptor attachment site for poliovirus⁸³.

A virus must be stable in the extracellular environment during transit between hosts, but also must be destabilized once it has bound to or entered the host cell, shedding its protein coat to allow infection to proceed. In rhinoviruses and polioviruses, the need for reversible stabilization appears to be fulfilled by the binding of a small cellular aliphatic molecule, the 'pocket factor' into a hydrophobic pocket in VP1. In major group of rhinovirus serotypes, the binding site for ICAM-1, the virus receptor, overlaps with the binding site of the stabilizing pocket factor. Virus attachment is, therefore, a competition between two equilibria – (i) binding of the pocket factor into the pocket and (ii) binding of the receptor into the canyon. Provided that receptor competes successfully with the pocket factor, many pocket factors will be lost as receptor molecules are recruited, destabilizing the virus as a prelude for uncoating. Certain antiviral compounds also bind in the hydrophobic pocket, displacing the pocket factor. If the affinity of an antiviral compound for the pocket is higher than that of ICAM-1, the antiviral compound will prevent receptor attachment and uncoating. Drug escape mutations in VP1 that improve

binding affinity for ICAM-1 can shift this balance, overcoming the antiviral effect (Figure 12).

ACKNOWLEDGEMENTS. This article is a slightly shortened version of a review in a book on *Structural Biology of Viruses*, edited by Wah Chiu, Roger Burnett and Robert Garcea. I am greatly indebted to Jeffrey Greve, Roland Rueckert and Prasanna Kolatkar for their dedicated help in writing that review with me. I especially thank Roland Rueckert for the long and fruitful collaboration I have had with him since 1981. Similarly, I have had equally happy and beneficial collaborations with Mark McKinlay, Guy Diana, Frank Dutko and Dan Pevear of the Sterling-Winthrop Pharmaceuticals Research Division; as well as with Jeffrey Greve of Miles Inc. I am particularly delighted with the success Prasanna Kolatkar has had in forming viable complexes of HRV and ICAM, and the outstanding work done by Tim Baker, Norm Olson, Holland Cheng and others at Purdue University in the electron microscopy studies. I am grateful to Tom Smith for preparation of Figures 3, 6 and 7 and Mark O'Neil for preparation of Figures 1, 4 and 12. There have been numerous postdoctoral fellows and graduate students involved in data collection trips to the Cornell High Energy Synchrotrons Source (CHESS) and other synchrotrons where we have had outstanding assistance. Lastly, but by no means least, I thank Cheryl Towell and Sharon Wilder in the preparation of this manuscript. The work was supported by a National Institutes of Health grant and a grant from the Sterling-Winthrop Pharmaceuticals Research Division to M.G.R. and a Lucille P. Markey Foundation Award for the expansion of structural studies at Purdue University.

Multidrug resistance: An emerging threat

Rajendra Prasad, S. Krishna Murthy, Ramasare Prasad, Vinita Gupta and Sneh Lata

School of Life Sciences, Jawaharlal Nehru University, New Delhi 110 067, India

Multidrug resistance (MDR) has been the main cause of failure of cancer chemotherapy where it is defined as the tendency of tumour cells to exhibit simultaneous resistance to unrelated chemotherapeutic agents. MDR has been mainly associated with the overexpression of an ATP binding cassette (ABC) protein, P-glycoprotein. Research in the past decade has revealed that the MDR phenomenon is not restricted to mammalian cells but rather occurs throughout the evolutionary scale. Thus over hundred ABC proteins have been characterized in mammals, bacteria and yeast. This review briefly describes the advancement in this field and identifies the problems which have emerged due to MDR.

MULTIDRUG resistance, which is a major problem in medical and agricultural developments, is an emerging phenomenon observed in various organisms throughout the evolutionary scale. In agriculture, the control of resistance of plant pathogens towards natural plant defence toxins and other common fungicides, as well as the emergence of parasite-toxin resistant crops, are of major economic importance. In medicine, the problem of cancer is compounded by the acquisition of multidrug resistance (MDR) by human malignancies. MDR has been one of the principle causes of failure of cancer chemotherapy where it can be defined as the tendency of tumour cells in patients and cultured cells to exhibit simultaneous resistance to multiple chemically unrelated chemotherapeutic agents^{1,2}. The elucidation of the mechanism by which tumour cells develop resistance to toxic effects of potent chemotherapeutic agents has revealed a great deal about the process of drug uptake, metabolism and extrusion. This has also provided basic insights into cellular process such as regulation of gene expression and gene amplification¹⁻³. It has been shown that overexpression of certain ATP-binding cassette (ABC)-proteins in prokaryotes and eukaryotes is linked to drug resistance phenomenon⁴. The well characterized mammalian protein MDR1 (P-glycoprotein) is associated with the development of a drug-induced multidrug resistance phenotype in tumour cells¹⁻⁵. Further, overexpression of *Ldpgp A* from *Leishmania* is responsible for methotrexate and heavy metal resistance, and *Plasmodium Pfmdr* has been implicated in chloroquine resistance in the malarial parasite⁶⁻¹⁰. Likewise, bacterial erythromycin resistance in *Staphylococcus* is caused by *MsrA* overexpression,

and the ABC-protein *DrrAB* of *Streptomyces* appears to be daunomycin resistance determinant^{11,12}.

Drug resistance

In mammalian cells

Selective passage of specific molecules across membrane is the key to cell's survival which is achieved by specific membrane transporters. The importance of membrane transport is becoming even more apparent from genome sequencing projects where a majority (20-30%) of genes have been found to encode for membrane and particularly transport proteins¹³. It has been shown that there exists a limited number of transporter families where member proteins of a family are related to each other in sequence and in molecular mechanism and probably have a common evolutionary origin^{11,12,14}.

It is now clear that a major mechanism of MDR in mammalian cells involves the overproduction of a 170 kDa plasma membrane glycoprotein, P-glycoprotein^{1,5,15}. This protein appears to cause MDR via an ATP-dependent drug efflux mechanism, which prevents the intracellular accumulation of drugs to an effective cytotoxic concentration¹⁻³. P-glycoprotein is a member of super gene family of bacterial and eukaryotic transporter proteins (Table 1). The mammalian P-glycoproteins are encoded by small families of linked genes, two in humans, three in rodents. The human *MDR1* gene, the *mdr1* and *mdr3* genes of mice and the *pgp1* and *pgp2* of hamster encode related proteins which transport hydrophobic drugs^{1,3,16}.

Cloning and sequencing was a major step towards understanding the structure and function of P-glycoprotein. The sequence encoding P-glycoprotein revealed that it is a tandemly repeated molecule of about 1280 amino acids (~170 kD). Each half consisting of a large hydrophobic domain containing three pairs of putative membrane-spanning α -helices and a conserved hydrophilic cytoplasmic domain containing an ATP-binding site^{1,17-20}. It has been proposed that the 12 transmembrane domains associate to form a pore or channel through which P-glycoprotein actively effluxes drugs^{1,5}. *In vitro* mutagenesis of the putative ATP-binding sites suggests that both sites are required and these may functionally interact to affect drug efflux^{1,21}.

Although the mechanism of drug transport has not

REVIEW ARTICLES

been defined, it is thought that direct binding of the drug to P-glycoprotein could be one of the essential steps¹. Extensive genetic manipulation involving deletion and insertion analyses of human MDRs has revealed that there are several coding regions which appear to have no effect on drug binding and specificity. However, there are several point mutations scattered throughout the gene which selectively alter drug specificity of the P-glycoprotein²¹. The drug specificity of MDR is a complex phenomenon which either requires a highly ordered structure or is affected by multiple independent parts of the protein molecule^{22,23}.

The ability of drugs and reversing agents to inhibit each other's binding to P-glycoprotein suggests that they

compete for common binding site(s)¹ (Table 2). Thus, one mechanism of MDR reversal by chemosensitizers and non-toxic drug analogues may be explained on the basis of competition for drug binding, which results in a decrease in efflux rate and a higher intracellular level of toxic drugs in MDR cells²¹. The P-glycoprotein recognizes a diverse group of substrates and shows different cross reactivity profiles¹⁻³. It is believed that a spontaneous mutation in P-glycoprotein gene, leading to altered drug specificity, may change the overall MDR profile^{1,21-25}.

That other mechanisms may also generate diversity in MDR phenotype has not been completely ruled out. In rodents, two different P-glycoproteins confer MDR

Table 1. Multidrug resistance pumps identified from microbes to man*

Mitomycin C			
Taxol			
Topotecan			
Many others			

and differential expression of these genes probably could alter the stoichiometry of the individual isoform in the cell membrane, resulting in differences in profile of transported drugs²⁶. Furthermore MDR is a result of overexpression of P-glycoprotein gene which may be accompanied by the coexpression of very large stretches of flanking DNA. In Chinese hamster cell line, P-glycoprotein amplification has been shown to be over one mega base pair in size and at least six classes of genes have been found to be coamplified and overexpressed^{3,27,28}. It is, therefore, possible that overexpression of such linked gene may modify the drug resistance profile. Differences in drug resistance profile may also be the result of differences in post-translational modification of P-glycoprotein molecules itself^{3,26}. It has recently been found that P-glycoprotein is phosphorylated at both serine and threonine residues^{5,26}. It has been speculated that the extent of change in phosphorylation may modulate P-glycoprotein mediated drug transport mechanism. However, this remains to be confirmed. Study of P-glycoprotein glycosylation suggests that carbohydrate molecules do not affect drug resistance⁵. However, their role as modulators of P-glycoprotein function cannot be precluded.

In bacterial cells

When antibiotics like penicillin were discovered, some fifty years ago, they were treated as miracle drugs of the century. This scene has suddenly changed. We are now confronted with new resistant types of bacteria. Once bacteria have learnt a particular strategy to circumvent the toxic effect of an antibiotic, they exchange

the genetic information, without any species specificity, with other bacteria. As a result, now with every possible bacterial infection, resistance to antibiotic treatment is a common phenomenon. The cause of resistance is attributed to the amplification of bacterial MDR genes.

Most bacterial MDR come under major facilitators families (MFS) which include arabinose/H⁺ symporter of *Escherichia coli* and glucose facilitator of eukaryotes^{11,12}. The proteins of this family are similar to P-glycoprotein of eukaryotic cells but lack ATP binding domains and thus are not classified as ABC proteins. MFS have 12 transmembrane α -helical domains and use proton motive force as a source of energy. QacA is one of the first MDR proteins identified in bacteria. *Staphylococcus* acquires resistance to the quaternary ammonium compounds (QacA) used in antiseptics. QacA is a membrane pump which effluxes out several drugs in a proton motive force dependent manner^{11,29}. *emrA* and *emrB* are the two genes coded by *E. coli* which confer resistance to uncouplers (CCCP) and other antimicrobial agents^{11,30}. Interestingly, EmrB protein is homologous to QacA. EmrA, on the other hand, is homologous to HlyD (a component of *E. coli* hemolysin efflux pump) albeit to a lesser degree. The function of these proteins is to form a channel between the inner and outer membrane (Figure 1). In case of hemolysin pump, HlyB is the actual pump while HlyD and a porin (TolC) are needed to form a channel to allow the passage of the peptide outside the cell. Thus, the topological design of EmrA-EmrB could be the same as that of hemolysin pump¹² (Figure 1).

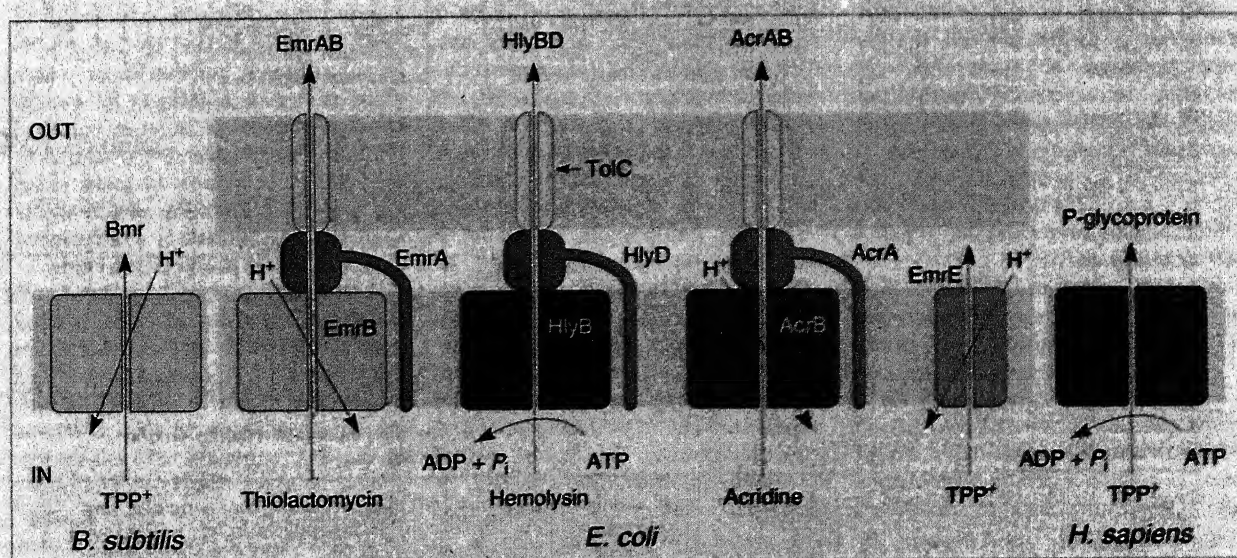

Figure 1. Topology of bacterial and human multidrug resistance. For comparison, the use of same colour indicates the homologous proteins in different MDR complexes. Reproduced from ref. 2 with permission.

REVIEW ARTICLES

In yeast cells

Multidrug resistance phenomenon is not restricted to mammalian or microbial cells. Host of genes homologous to MDR have been identified in yeasts during the past three decades. Yeast shares similarity in structural and functional organization with higher eukaryotes and is amenable to genetic manipulations and thus, serves as an excellent model for unravelling eukaryotic pathways of MDR. The studies involving MDR in yeasts have got further impetus since some yeast species are also pathogenic to plants and humans. Already about 25 genetic determinants associated with multidrug resistance

(pleiotropic drug resistance, PDR in yeasts) have been characterized in *Saccharomyces cerevisiae*, *Schizosaccharomyces pombe* and *Candida albicans*^{31,32}. The gene products encoded by these yeasts fall into three classes of proteins: ABC, MFS and transcription regulators (Table 3).

The *PDR5* gene was cloned as a multicopy plasmid borne DNA fragment capable of conferring pleiotropic drug resistance (PDR)^{33,34}. The gene codes for a polypeptide of 1511 amino acid residues with calculated mol. wt of 170.4 kD. PDR5 protein is predicted to contain twelve 'integral' transmembrane spans gathered in two groups of six contiguous membrane spans. Each hydro-

<i>S. cerevisiae</i>	ZRC1	Zn, Cd	Transporter

Drugs are abbreviated as follows: atr, aminotriazole; amy, antimycin; aml, amiloride; ben, benomyl; bor, borrelidin; caf, caffeine; chl, chloramphenicol; cyh, cycloheximide; ery, erythromycin; flu, fluphenazine; hygB, hygromycin B; lep, leptomycin; mic, miconazole; muc, mucidin; nin, 1-nitroso-2-naphthol; MNNG, *N*-methyl-*N'*-nitrosoguanidine; 4-NQO, 4-nitroquinoline *N*-oxide; ner, neutral red; met, methotrexate; oli, oligomycin; phe, 1-10-phenanthroline; smm, sulfomethuron methyl; sts, staurosporine; tet, tetracycline; val, valinomycin; van, vanadate; tri, triaziquone; tre, trenimon. Other abbreviations are: NBD, nucleotide binding domain; TM, transmembrane region; ABC, ATP-binding cassette; (NBD-TM)2, NBD precedes TM and vice versa and has 2 halves. The table is compiled from refs 31, 41, 42.

phobic domain follows a hydrophilic region including a predicted ATP-binding cassette (ABC). Thus, PDR5 seems to have duplicated structure, consisting of two halves each composed of one hydrophilic and a hydro-

phobic domain^{34,35} (Figure 2). The two similar ABC domains of PDR5 are conserved within a large super family of transport proteins³⁵.

A sequence alignment of entire protein in databanks revealed homology between PDR5 and other members of the ABC-transporters superfamily. The best comparison was obtained with yeast ADP1, pheromone transporter STE6, *Drosophila* white and brown eye pigment transporter, bacteria hemolysin secretion protein B, mouse MDR1, rat major histocompatibility complex Mtp1 and most importantly with cystic fibrosis protein CFTR in humans. The region of homology is mainly localized on ABC cassette³⁴ (Figure 2). Recent evidences for the modular structure of a four-domain ABC transporter have been provided by domain dissection analysis of the yeast STE6 transporter^{36,37}. The two halves of the molecule were shown to be able to support, jointly, 'a' factor transport activity³⁸.

A *PDR5* homologue *CDR1* has recently been cloned and characterized in a pathogenic yeast, *Candida albicans*, by functional complementation of a *PDR5* null mutant of *S. cerevisiae*. The nucleotide sequence of *CDR1* revealed that, like *PDR5*, it encodes a putative membrane pump belonging to ABC superfamily³⁹ (Figure 2). Fresh evidences from our group suggest that there are several homologues other than *CDR1* in *C. albicans* which display cross resistance pattern different from *CDR1* and *PDR5*^{39,40}. Benomyl resistant (*Ben^r*) gene of *C. albicans* has also been shown to encode a putative membrane pump which belongs to MFS family⁴¹. The characterization of *CDR1*, *Ben^r* and identification of several other multidrug resistance genes from a pathogenic yeast could pave the way for tackling drug resistance in *Candida* and for the development of effective anti-*Candida* drugs. Recently, the field of drug resistance in pathogenic fungi has generated considerable interest because of spread of AIDS where *Candida* infections are most predominant.

A few ABC proteins have also been characterized in a fission yeast, *S. pombe*. HMT1 is a duplicated ABC protein associated with the vacuolar membrane and most similar to mammalian glycoprotein. Overexpression of the *HMT1* was correlated to enhanced heavy metal tolerance⁴². The *PMD1* encodes a half ABC protein (comprising of six transmembrane segments) homologous to *MDR1* and *STE6*. Overexpression of *PMD1* confers resistance to leptomycin B, cycloheximide and valinomycin³¹. HBA2, another ABC protein that confers resistance to brefeldin A and other drugs, has recently been identified in *S. pombe*⁴³.

The two pleiotropic drug resistance loci, *PDR1* and *PDR3*, were found to encode homologous transcription factors belonging to the family containing a 'Zinc 2 Cysteine 6' co-ordination complex in the DNA binding domain³². The *PDR1* gene product was shown to modulate

Figure 2. Predicted structure of the CDR1, PDR5, STE6 and MDR1 proteins. The CDR1 and PDR5 proteins are predicted to be composed of two repeated halves, each comprising of one hydrophilic domain followed by a hydrophobic domain. Two hydrophilic domains are cytoplasmic (IN) and each contains one ATP-binding site. The two hydrophobic domains are considered to be spanning the membrane. The sequence of domain inversion between CDR1 and STE6 can be seen.

the expression of multidrug resistance genes, such as *PDR5* and *STE6*, and also affect the estradiol levels^{32,44}. The fact that estrogen molecules are also substrates in the yeast *PDR* pathway, may provide a link between drug resistance and hormone tolerance³². The uncovering of regulatory elements, like *PDR1*, *PDR3*, etc. in yeast^{45,46}, might provide the basis for unravelling related circuits of control in human multidrug resistance.

Physiological role of P-glycoprotein

The availability of various sequences of P-glycoprotein genes of different species has allowed a comparison between different genes, both within a species and among different species. The comparison has shed some light on the evolution of P-glycoprotein and the organization of its gene. The similar organization of coding sequences and intervening sequences in different genes from the same species indicate that the internal duplication of the ancestral gene occurred prior to the formation of multigene family. The organization of homologous members of the multigene family in different mammalian species suggests that the formation of a multigene family preceded the divergence of species³. The evolutionary relation and conserved structure of P-glycoprotein leads to questions like: what is the physiological function of such proteins?

Expression of P-glycoprotein is cell and tissue-specific^{2,47,48}. Therefore, the tissue distribution may help to identify the physiological role of P-glycoprotein as a transporter. But given the specific and complex pattern of expression, it has been difficult to imagine a single class of physiological substrate². Therefore, it has been suggested that P-glycoprotein plays a diverse role in transport²³. However, as of now there are only a few examples from higher eukaryotes where the physiological role of MDR proteins has been identified (Table 4).

Mechanisms of MDR

Multidrug transporter (ABC type) does not function as a simple transmembrane transport system which effluxes out drugs from cytoplasm to extracellular space. Most of the substrates of pump are hydrophobic and thus tend to partition in nonpolar environment in preference to aqueous phase. Indeed, the data also suggest that anticancer anthracyclines, rhodamine-123 are predominantly localized in the plasma membrane and intracellular membranous structures in addition to their targets. The spectrum of drugs handled by the transporter suggests that a simple model of substrate recognition may not be correct. At least one transporter of ABC family CFTR (cystic fibrosis transmembrane regulator) is also a Cl⁻ channel⁴⁹⁻⁵¹. Therefore, a need to have a model

of P-glycoprotein transporter which encompasses all the conflicting observations has been realized⁵².

According to the most accepted model, drugs are removed by the transporter directly from the plasma membrane (lipid bilayer), thus, drugs are thrown out and are unable to reach the cytoplasm². Conceptually, the multidrug transporter works as a 'hydrophobic vacuum cleaner' which removes drugs from the membrane. The mechanism of energy transduction during drug transport is, of course, not clear. The nucleotide-binding domains of P-glycoprotein and constitutive ATPase activity therein do suggest a role of nucleotide hydrolysis. Some evidences also suggest that the drug transporter could be an enzyme 'flippase' which would bind the drug from the inner leaflet and flips it to the outer leaflet from where the drug diffuses out to extracellular space or the pump could behave like a moving 'water-wheel' or 'escalator', which expels all membrane constituents of approximately similar size (molecular weight) and shape, with little substrate specificity. There is still no unifying model which could include all conflicting observations of drug transport^{1,2,26} (Figure 3). But the recent suggestion of chloride channel activity associated with the multidrug transporter is consistent with the idea that the net positive charge (proton) accompanies drugs out of the cell and this may require an anion channel to maintain electric neutrality².

Future perspective

In the beginning a specific mechanism of antibiotic resistance was thought to be more important. Thus attempts were made to produce more effective antibiotics by modification of specific groups of antibiotic molecules in order to make them inert as potential substitute for commonly occurring antibiotic inactivating enzymes. However, the presence of more generalized mechanism of multidrug resistance has compelled the scientists to evaluate this strategy. As a result, several new drugs with new targets are in the pipeline and may hit the market in couple of years' time. Since these new drugs hit new targets it is hoped that bacteria will take still longer to learn to destroy them. There is also a need to obtain more knowledge about the substrate-binding process of these transporters. A possible approach would be to increase the spontaneous influx of drugs by making them sufficiently lipophilic so that efflux can be counter balanced by rapid influx. Indeed, it will be a major challenge for the pharmaceutical industry because some of the multidrug efflux systems seem to pump out almost any amphiphilic compound.

In plant pathogens, P-glycoprotein may be responsible for the secretion of fungal pathogenesis factors or toxic plant defence products playing a crucial role in plant-pathogen interaction. Understanding of the role of P-

glycoprotein in these processes would open new ways for indirect control of plant pathogens by interference with the plant-pathogen interaction. This particular area is still at its infancy. In this regard, recent cloning of a MDR homologue in *Arabidopsis thaliana* and identi-

fication of efflux pumps in pathogenic fungi of plants are interesting developments⁵³⁻⁵⁵.

In mammalian cells, where numerous approaches to reverse or modify MDR are currently being investigated, two important problems need to be re-emphasized:

Table 4. Some of the ABC-proteins with known substrates

Species	Protein	Substrate	Function
Bacteria			
<i>Salmonella typhimurium</i>	Opp ABCDF	Oligopeptides	Import
<i>Streptococcus pneumoniae</i>	Ami ABCDEF	Oligopeptides	Import
<i>Bacillus subtilis</i>	Opp (Spo K)	Oligopeptides	Import
<i>E. coli</i>	Dpp	Dipeptides	Import
<i>Bacillus subtilis</i>	Dci A	Dipeptides	Import
<i>S. typhimurium</i>	His JQMP	Histidine	Import
<i>E. coli</i>	His JQMP	Histidine	Import
<i>E. coli</i>	Mal EFGK	Maltose	Import
<i>S. typhimurium</i>	Mal EFGK	Maltose	Import
<i>Enterobacter aerogenes</i>	Mal EFGK	Maltose	Import
<i>E. coli</i>	Ugp ABCE	Gly-3-Phosphate	Import
<i>E. coli</i>	Ara FGH	Arabinose	Import
<i>E. coli</i>	Rbs ACD	Ribose	Import
<i>E. coli</i>	Gln HPQ	Glutamine	Import
<i>S. typhimurium</i>	Pro U (VWX)	Glycine-betaine	Import
<i>E. coli</i>	Pro U (VWX)	Glycine-betaine	Import
<i>E. coli</i>	Liv HMGF (JK)	Leu-Ile-Val	Import
<i>E. coli</i>	Pst ABC	Phosphate	Import
<i>Pseudomonas stutzeri</i>	Nos DYF	Copper	Import

Figure 3. A model of MDR transporter. The drug is probably detected by the transporter within the lipid bilayer. Both uncharged (A) and charged (B) species of drugs could be the substrate for the transporter. The blue-coloured domains of protein indicate the ATP-binding sites. The red molecules are drugs and green molecules are putative physiological substrates for the transporter.

(i) MDR is unlikely, if ever, to be solely due to P-glycoprotein-mediated resistance, and (ii) P-glycoprotein is expressed by a very wide range of normal, noncancerous tissues as well. In the first case, therefore, prospective clinical protocol aimed at circumventing MDR may have to encompass more than just anti P-glycoprotein therapy. In the second case, successful anti-MDR therapy will probably have to be restricted to P-glycoprotein expressing tumour cells, to prevent unknown potentially deleterious consequences of inhibiting P-glycoprotein action in the normal healthy tissues.

RESEARCH ARTICLE

Evidences of Late Quaternary neotectonic activity and sea-level changes along the western continental margin of India

V. Purnachandra Rao, M. Veerayya, M. Thamban and B. G. Wagle

National Institute of Oceanography, Dona Paula, Goa 403 004, India

The offshore data on sea-level changes along the western margin of India have been reviewed and evidences of Late Quaternary neotectonic activity and subsidence are documented, based on the diagenetic textures of limestones from deeper submarine terraces and from the Fifty Fathom Flat off Saurashtra-Bombay, authigenic clays from the Kerala continental margin and onshore data. Offshore sea-level data relative to the eustatic sea-level show about 40 m subsidence sometime in the Holocene. Existing sea-level curves may not reflect the true sea-level changes. As there are several gaps in the data base, it is suggested that more systematically collected offshore data is an immediate requirement to chart the accurate sea-level changes and construct a regional sea-level curve for the Late Quaternary.

SEA-LEVEL change in a given area is governed by eustatic sea-level fluctuations and local factors such as land

movements by tectonic and isostatic adjustments and geoidal variations^{1,2}. The construction of regional sea-level curve is therefore essential and important in understanding the implications of sea-level changes. Kale and Rajaguru³ and Hashimi *et al.*⁴ constructed sea-level curves for the Late Quaternary for the western continental margin of India. These curves differ distinctly from one another and also with the eustatic sea-level curve of Fairbanks⁵ (Figure 1). The authors used some estimated³ and inferred ages⁴ for making sea-level curves. Incidentally, the actual radiocarbon dates of the samples from the western offshore (outer shelf and slope) (Figure 2) are younger than those at corresponding depths on the eustatic sea-level curve (Table 1) and thus plot away from all the above curves (see Figure 1). This may be due to neotectonism which was not considered in preparing the sea-level curves. In this article we provide evidences of Late Quaternary neotectonism along the western margin of India and reassessment of existing

Deeper terrace limestones

Rao and Veeraya⁶ reported 1.5 to 2.0 km wide submarine carbonate terraces at 130, 145 and 170 m water depths on the continental slope off Saurashtra–Bombay (Figure 3). These terraces lie below the eustatic sea-level low (–120 m)⁵ during the Last Glacial Maximum (LGM). The radiocarbon dates and diagenetic textures of the limestones from 130 m terrace indicate that these sediments were cemented into limestones at intertidal conditions at about 11,890 years BP. The eustatic sea-level was, however, at –90 m at about 12,000 years BP (ref. 5). Transportation of limestones from shallow shelf

Figure 1. Sea-level curves and plot of radiocarbon dates of the samples from the western offshore. Note that the ages of the samples plot away from the curves. Fairbanks curve (ref. 5) is for the Barbados Islands; the ages of the coral samples used for the curve were corrected with the uplift data of the Barbados and for local sea water (Fairbanks sea-level curve is being used as a reference eustatic sea-level curve by several workers all over the world). The dotted line may represent sea-level change between 12,000 and 9,000 years BP.

depths can be precluded, because the terraces on landward are covered by 15–20 m thick sediments (Figure 3) and the ages of samples from the adjacent shelf are younger by about 2,000 years and nowhere else are these ages found (see Figure 2). It is therefore suggested that these deeper terraces on the Saurashtra–Bombay margin might have been positioned at water depths < 120 m during the LGM and subsided to the present position sometime after 12,000 years BP.

Radiocarbon dates and their comparison. The age of the aragonite sands and limestones on the carbonate platform ranges from 10,400 to 8,340 years BP and 9,200 to 8,465 years BP, respectively (see Table 1; Figure 2). There is no relationship between ages of the samples and their depth of occurrence and the sediments having younger ages occur even at greater depths. Further, the sediments and limestones with an age difference of about 2,000 years occur in the vicinity on the platform.

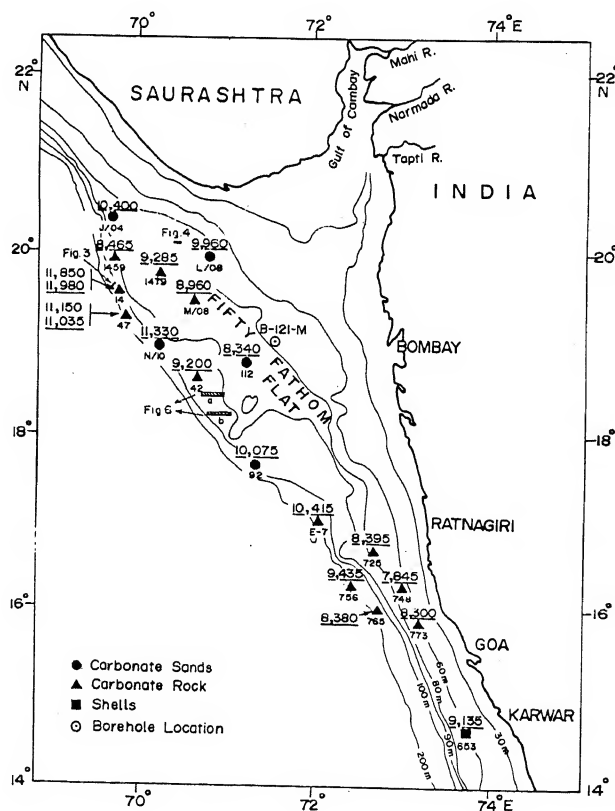

Figure 2. Sample location map of west coast of India, numbers underlined are radiocarbon ages. The location of deeper submarine terraces (Figure 3), *Halimeda* bioherms (Figure 4) and sand ridges (Figure 6) are also shown here.

Table 1. Available radiocarbon dates on surficial carbonate samples from the western continental margin of India (see Figure 2 for sample location)

Sample no.	Nature of sample	Depth (m)	Age (years BP) and reference	Age (approx.) on the eustatic sea-level curve ⁵ for the corresponding depth
47	Algal-pelletal l.st.	150	11,150 ± 130 (refs 8, 9)	—

765	—	97	8,380 ± 140 (ref. 36)	12,900

*These points are not plotted in Figure 1.

Several samples (about 90 m depth) on the carbonate platform yielded ages of about 9,000 years BP. Contrastingly, the shells dated 9,135 years BP were collected at 58 m depth on the continental shelf, south of the carbonate platform (see Figure 2). Therefore, there is no particular trend in the data when viewed the ages of unconsolidated sediments and rocks together (Figure 2). The ages on the platform are younger than those at corresponding depths on the eustatic sea-level curve (Table 1) and with the data on the east coast of India. For example, the platform lies between 80 and 90 m depth and the sample ages range from 10,400 to 8,340 years BP. The eustatic sea-level for the corresponding ages was, however, at depths between 65 and 30 m, respectively⁵. Similarly, the ages of the terraces at 80 and 100 m water depth on the eastern shelf of India are 10,790 and 12,530 years BP⁷. The samples corresponding to these ages, however, occur at about 130–150 m water depth on the western margin (Table 1). These anomalies need to be explained based on the nature of sediments.

Constituents and topographic features. Several workers^{8–12} referred to the carbonate (aragonitic) sands and limestones on the platform as oolites and oolitic limestones. If these sands are oolites (chemical precipitates), formed during the Holocene transgression, one would expect older ages seaward and younger ages landward of the platform. This, however, is not evident in Figure 1.

There are several dates on the platform showing an age 10,000–9,000 years BP during which the eustatic sea-level rise was very rapid (23 m/1000 years)⁵. As the formation of oolitic coating is a slow chemical process¹³, it may be difficult to achieve prerequisite conditions (supersaturated aragonite in the waters and maintaining < 10 m depth) for oolite formation at this high rate of sea-level rise. Even if oolites are present at places (possibly associated with terraces or thin oolitic coating formed after 9,000 years BP), large nucleus material determines the radiocarbon ages and one has to find a suitable explanation for the origin of large homogeneous aragonitic nucleus that formed prior to the oolitic coating; this explanation, however, is lacking from the above references. So, referring to the carbonate sands on the platform as oolites does not explain the anomalous distribution of radiocarbon dates (Figure 2). Even if oolitic sediments occur locally, their ages should not be used for the construction of sea-level curve as oolites are unreliable sea-level indicators¹⁴.

A recent study¹⁵ based on bathymetry, seismics and side scan sonar data and on petrology of the sediments and sedimentary rocks has demonstrated the presence of Late Quaternary *Halimeda* bioherms (Figure 4) on the Fifty Fathom Flat. *Halimeda* (Figure 5A) contributed aragonite sediments to the platform. The following points have emerged^{15,16}: (i) High energy environments prevailed during the *Halimeda* growth. (ii) The aragonite muds derived from *Halimeda* were fixed in the form of faecal

Figure 3. Deeper submarine terraces on the continental slope off Saurashtra-Bombay (see Figure 2 for location). T, terraces; M, multiple.

Figure 4. *Halimeda* bioherms on the Fifty Fathom Flat (see Figure 2 for location).

pellet sand (Figure 5B) mainly by Crustaceans. (iii) Reworking of aragonitic sands in high energy environments led to the exposure of older sediments at certain depths (see Figure 2). (iv) *Halimeda* growth continued locally at places until 8,300 years BP, resulting *Halimeda* limestones having younger ages at seaward edge of the platform (see Figure 2). (v) The limestones dated 9,200 years collected at 85 m depth on the platform exhibit vadose diagenetic conditions.

Well-defined submarine sand ridges have also been reported near the shelf break and on the carbonate platform where *Halimeda* bioherms profusely occur¹⁷. These ridges are 1.5 to 18 m high, 0.5 to 10 km wide, several tens of km long, a few kilometers apart and trend almost parallel to the shelf edge (Figure 6). Some broad elongated ridges are superimposed by sand waves/bed forms having heights in the order of 1–2 m

and wavelength 50–300 m. Wagle and Veerayya¹⁷ suggested that these are relict nearshore sand ridges formed in high energy environments where water depths were shallower and tidal and wave-induced currents were stronger.

Since the material that formed sand ridges is aragonite sands which comprise of abundant *Halimeda* fragments and faecal pellets, it is obvious that the *Halimeda* growth on the platform might be prior to and had continued during the sand ridges formation. Both sand ridges and *Halimeda* bioherms indicate high energy environments and the former are distinct towards the edge of the shelf (Figure 6). It is difficult to assess the depth limits for *Halimeda* bioherms, because *Halimeda* normally grew at much shallow depths (< 20 m). However, their growth at depths > 50 m towards the edge of the shelf¹⁸ and certain species of *Halimeda* at 120–150 m depths¹⁹ have also been reported. Reworking exposed older sediments at places. Therefore, the radiocarbon ages of the unconsolidated sediments from the platform may not be of much use in reporting sea-level changes. It has been suggested that all shallow water deposits are not necessarily sea-level indicators and caution be exercised in selecting the sea-level indicators^{1,2}. The depth precision of the sea-level indicators should be well defined before being used for sea-level changes.

Diagenetic textures of the limestones. *Halimeda* limestones dated 8,465 years BP occur towards shelf edge and exhibit marine cements¹⁵. These were similar to subtidal limestones²⁰, wherein pumping of sea water into the pores of the sediments results in cementation. The limestones at 85 m water depth exhibit vadose diagenetic textures, suggesting vadose conditions on the platform at about 9,200 years BP (refs 15, 16). The mineralogy

and stable isotopes¹⁵ suggest that these samples are reliable sea-level indicators. However, the eustatic sea-level was at -40 m at about 9,200 years BP. The differences in the depths thus suggest subsidence of the platform. In fact, the deeper submarine terraces (evidence 1) lie seaward of the platform (see Figure 2) and the samples both from terraces and platform support neotectonic activity. It is not known whether the neotectonic activity after 12,000 years was single or episodic. Sampling on deeper terraces from the slope and other recently described shelf terraces²¹ may yield better information.

Onshore data

There are no samples dated <8,000 years BP, yet available from the offshore. The youngest age so far reported from the calcareous deposits on the outer shelf (Figure 2) and peat/wood from the inner shelf (discussed

below) is 8,300 years BP. It is still unknown the position of the sea-level at 8,300 years BP from the offshore data. On the other hand, Patel *et al.*²² (cf. Merh²³) reported the Early Holocene high sea-level (+8 to +10 m above the present sea-level) in coastal Gujarat and Maharashtra that gradually regressed to the present position at about 6,000 years BP. Sukhtankar²⁴ reported Holocene marine terraces at 4 m above the present sea-level along Maharashtra coast. They could not indicate the exact time of high sea-level during the Early Holocene. Bruckner²⁵ identified marshy soils dated 7,600 years BP, off Gujarat, lying 1.5 m above the sea-level. Juyal *et al.*²⁶ reported oyster reefs at 1-3 m elevation whose ages range from 2,000 to 8,000 years BP, suggesting high sea-level during Early Holocene on the Saurashtra coast. The absence of data <8,000 years BP, from the offshore and the presence of corresponding (Early Holocene dated samples) data in the coastal region imply that the sea-level was already at and above present sea-level by 8,000 years BP. The eustatic sea-level was, however, at -24 m at 8,000 years BP (ref. 5). These differences in depths again indicate possible neotectonism at about this time.

Authigenic clays

Verdine and glaucony are two authigenic green clay mineral facies occurring in tropical shallow marine environments. Verdine occurs at depths < 60 m and glaucony occurs seaward of verdine at depths²⁷ > 60 m. Phyllite V and Phyllite C are the mineral phases of the verdine facies. As verdine is susceptible for alteration, it gets destroyed easily in older surficial marine sediments and therefore it has been found so far to be only of Late Quaternary age²⁷. The depth distribution of verdine and glaucony facies has been verified and used for the reconstruction of palaeogeography of the continental margins during the Late Quaternary²⁷.

The distribution of green grains on the Kerala continental shelf and slope (Figure 7) shows that verdine occurs at depths between 40 and 280 m followed by glaucony down to 420 m depth²⁸. It has been suggested that the verdine and glaucony facies on the continental

Figure 5. A, Sections of *Halimeda* (a-k), echinoderm (l) and benthic foraminifers (m & n) from the limestones of the platform. Note rounding of *Halimeda* grains. *Halimeda* is aragonitic in composition. If sections are not made, the morphology of the grains can easily be confused with the faecal pellets or oolites. B, Faecal pellet-dominated aragonite sands from the platform.

Figure 6. Sand ridges on the continental shelf off Bombay (see Figure 2 for location).

Figure 7. Distribution of green grains on the eastern and western continental margin of India. Zone A is the depth range (0–60 m) for the formation of Present day verdine, zone B is the depth range (61–120 m) for verdine formed during Holocene transgression and zone C (120–180 m) is the depth range for verdine formed during the Last Glacial Maximum.

margin are diachronous and slope facies formed during LGM, when the sea-level was at –120 m, and shelf facies formed during the Holocene transgression²⁷. So the expected depth ranges for verdine and glaucony facies on the slope during the LGM are 120 to 180 (120 + 60) m and > 180 m, respectively. However, on the continental slope of Kerala verdine occurs down to a depth of 280 m. Verdine mineral at 100–205 m (phyllite V) and at 280 m (phyllite C) are different and rules out the possibility of lateral transport. So the distribution of verdine and glaucony facies on the continental margin off Kerala does not coincide with the suggested depth range. On the other hand, verdine facies occur at depths between 18 and 170 m followed by glaucony down to 247 m on the east coast of India²⁹. The range of green grain facies from verdine to glaucony at 170 m depth on the continental slope of the east coast of India (Figure 7) is well in agreement with the suggested depth ranges of these facies during the LGM, and also their distribution is similar to that on Senegalese and French Guinea margins²⁷. The distribution of verdine and glaucony on the west coast therefore appears anomalous and suggests that the paleogeography of the west coast was different during the Late Quaternary, pointing to the possible neotectonic activity. As these authigenic clays form in wide depth range, quantitative aspect of sea-level changes cannot be deciphered from them.

Reassessment of offshore data and sea-level curves

1. There is a paucity of data on sea-level changes for the periods between 18,000 and 12,000 years BP and

8,300 years BP to Present from the offshore region.

2. Although one should appreciate the efforts of earlier workers for attempting sea-level curves for the western margin of India with limited data, these curves may not work as they^{3,4} have used oolite ages and some estimated and inferred ages based on the presumption of oolites which are unreliable sea-level indicators¹⁴. They⁴ have also used radiocarbon ages (range from 9,630 to 8,300 years BP) of carbonized wood/peat^{30,31} from the inner shelf clays. (i) The peat dates are higher as it has been established that mangroves started growing on the tropical shelves world wide during Mid-Holocene and the Holocene peats are nowhere older than 7,000–5,000 years BP (ref. 32). (ii) It has been observed that the age of the peat layer from a core collected at 29 m depth is 9,630 years BP and another peat layer from a core collected deeper offshore at 40 m depth is 8,620 years BP (ref. 31). These dates should have been exactly opposite if peat is sedentary (a sea-level indicator) and if one is to trace the course of Holocene transgression on the western shelf. (iii) The peat ages on the inner shelf and ages of the carbonate deposits on the outer shelf (see Figure 2) are similar suggesting that one of them is allochthonous. The carbonate deposits are extensive on the platform, derived from the *Halimeda* bioherms and thus were not transported. The above points suggest that the peat in the inner shelf clays is most probably allochthonous similar to the peat reported by Mascarenhas *et al.*³³ in the inner shelf sediments off Karnataka and their ages thus do not qualify for the construction of sea-level curve.

3. There are several radiocarbon dates on algal limestones^{8,9,34–36} (Table 1). Unless the specific algae-forming

limestones are identified³⁷, these limestones alone cannot be considered as reliable sea-level indicators³⁸.

4. Since the diagenetic textures have been investigated for the limestones having ages between 12,000 and 9,000 years BP, this part of the curve is constructed and shown in Figure 1. A comparison of this with eustatic sea-level curve of Fairbanks⁵ reveals about 40 m subsidence on this margin sometime after 12,000 years BP. The rate of subsidence and timing of the Holocene neotectonic activity are yet to be established.

5. Practically little radiocarbon ages data exist for the SW continental margin of India.

Despite there were two international efforts (IGCP Projects 200 and 274) for obtaining sea-level data, the Indian continental margins have received very little attention and the construction of sea-level curve for this region is still at its infancy. Sea-level data is of crucial importance, because it provides knowledge on the past sea-level stands based on which we can accurately model and estimate the impact of sea-level rise as a consequence of global warming. More serious and concerted efforts by geomorphologists, sedimentologists and radiochemists are required and would be useful in obtaining this important information.

Aerodynamic performance of SUNYA and OSHO airfoils

P. Ramamoorthy

CTFD Division, National Aerospace Laboratories, Bangalore 560 017, India

The inverse design problem of an airfoil where one gets an airfoil for given velocity distribution has engaged the best brains. In revisiting this problem we discovered two new airfoils called SUNYA and OSHO. Aerodynamic performance of these airfoils is given using the existing codes.

In 1977 we gave an analytical airfoil representation¹ describing a symmetrical airfoil in terms of Wagner functions. This representation is given by

$$y' = f'(x) = \sum_{n=0}^{\infty} a_n h_n(x) - a_0, \quad (1)$$

where $f(x)$ describes the airfoil thickness distribution and dash denotes the differentiation w.r.t. x ; $h_n(x)$ are Wagner functions defined as follows:

$$h_n(x) = \frac{1}{\pi} \frac{T_{n+1}(1-2x) + T_n(1-2x)}{\sqrt{x-x^2}}, \quad (2)$$

where $T_n(1-2x)$ is the n th Chebychev polynomial. Properties of Wagner functions are given elsewhere². Figure 1 gives the airfoil geometry and Figure 2 gives the first five Wagner functions. It should however be noted that this expansion need not be a universal one.

Integrating (1) and ensuring the closure of the airfoil at the leading and trailing edges one gets the following representation of the airfoil:

$$f(\theta) = \frac{a_0}{\pi} (\theta + \sin \theta) - a_0 \sin^2 \frac{\theta}{2} + \frac{1}{\pi} \sum_{n=1}^{\infty} \left(\frac{\sin n + 1\theta}{n+1} + \frac{\sin n\theta}{n} \right) a_n, \quad (3)$$

where

$$x = \sin^2 (\theta/2). \quad (4)$$

At that time (1977), we had not realized that this representation has many important consequences for the airfoil design. Recently we³ showed that this expansion contains two new symmetrical airfoils called SUNYA and OSHO as follows.

$$y_{\text{sunya}} = \frac{a_0}{\pi} [2 \sin^{-1} \sqrt{x} + 2\sqrt{x(1-x)} - \pi x], \quad (5)$$

$$y_{\text{osho}} = \frac{a_0}{\pi} [2 \sin^{-1} \sqrt{x} + 2\sqrt{x(1-x)} - \pi x] + \frac{a_1}{\pi} \sqrt{x} (1-x)^{3/2}, \quad (6)$$

where a_0 and a_1 are constants describing the properties of these airfoils. It can be easily verified that OSHO airfoil is the superposition of SUNYA and JOUKOWSKI

Figure 1. Aerofoil geometry.

Figure 2. Wagner functions $h_n(x)$ for $n=0$ to $n=4$.

airfoils. It is interesting to compare these airfoils with other classical analytical airfoils given below

$$y_{\text{joukowski}} = \frac{4a_0}{\pi} \sqrt{x} (1-x)^{3/2}, \quad (7)$$

$$y_{\text{kar.trefftz}} = a_0(1-x)^{3/2} \sqrt{x} + a_1(1-x)x, \quad (8)$$

$$y_{\text{piercy}} = a_0 \sqrt{x} (1-x)[1 + a_1(1-x)]^{1/2}. \quad (9)$$

It is recalled that the three latter airfoils are obtained by conformal transformation methods.

In reference 3 we have shown how to use SUNYA and OSHO airfoils for analysis and design of any arbitrary symmetrical airfoil. The properties of these airfoils are given below.

Properties of SUNYA airfoil

- SUNYA airfoil is described by the equation (5) and is a single parameter airfoil, the parameter being a_0 .

The leading edge radius ρ_s is given by the equation

$$\sqrt{\frac{\rho_s}{2}} = 2 \frac{a_0}{\pi}. \quad (10)$$

The trailing edge angle β (positive with respect to negative x-axis) is given by the equation

$$\tan \beta = -a_0, \quad a_0 > 0. \quad (11)$$

- The maximum thickness position x_{max} is given by

$$x_{\text{max}} = \sin^2(\theta_m/2) = 0.2844,$$

$$\text{where } \theta_m = 2 \tan^{-1}(2/\pi). \quad (12)$$

- The maximum thickness is given by

$$t_{\text{max}} = 4(a_0/\pi) \tan^{-1}(2/\pi). \quad (13)$$

All the symbols and variables are defined in Figure 1.

Properties of OSHO airfoil

- OSHO airfoil is described by the equation (6).

Its leading edge radius ρ_{osho} is given by

$$\sqrt{\frac{\rho_{\text{osho}}}{2}} = \frac{2}{\pi} [a_0 + a_1]. \quad (14)$$

- The trailing edge angle β is given by the equation

$$\tan \beta = -a_0, \quad a_0 > 0. \quad (15)$$

- Maximum thickness position x_{max} is given by

$$x_{\text{max}} = \sin^2(\theta_m/2),$$

where

$$\frac{[2(1 + \cos \theta_m) - \pi \sin \theta_m]}{[\cos \theta_m + \cos 2\theta_m]} = -\frac{2a_1}{a_0}. \quad (16)$$

- The maximum thickness is given by

$$\begin{aligned} \frac{t_{\text{max}}}{2} &= \frac{a_0}{\pi} [\theta_m + \sin \theta_m] - a_0 \sin^2 \frac{\theta_m}{2} \\ &+ \frac{a_1}{\pi} [\sin \theta_m + 0.5 \sin 2\theta_m]. \end{aligned} \quad (17)$$

Figure 3. 15% SUNYA and OSHO airfoils.

Figure 4. Aerodynamic performance of 15% SUNYA and JOUKOWSKI airfoils ($M=0.1$, $R_e=3 \times 10^6$).

A 15% SUNYA airfoil is obtained by equation (5), where a_0 is obtained by the equation (13) by assuming $t_{\max}=0.15$. Table 1 gives the coordinates of this airfoil. Figure 3 shows this airfoil with 15% JOUKOWSKI airfoil superposed on it. NCSU code⁴ and Rokicki code⁵ are utilized for obtaining the aerodynamic performance at prestall and stalling angles of attack respectively. Figure 4 shows the results at design condition of $M=0.1$ and $R_e=3 \times 10^6$, where M and R_e are Mach number and Reynolds number respectively. The performance of a 15% JOUKOWSKI airfoil is also shown in this figure for comparison.

A 15% OSHO airfoil is obtained by assuming the maximum thickness point to be at $x_{\max}=0.28$ and $t_{\max}=0.15$ in the equations (16) and (17) respectively and evaluating a_0 and a_1 . The coordinates of this airfoil are also given in Table 1. This airfoil is also displayed in Figure 3 with 15% JOUKOWSKI airfoil superposed on it. Again NCSU and Rokicki codes are used for obtaining the aerodynamic performance of this airfoil. Figure 5 gives the results. The performance of the 15%

Figure 5. Aerodynamic performance of 15% OSHO and JOUKOWSKI airfoils ($M=0.1$, $R_e=3 \times 10^6$).

JOUKOWSKI airfoil is superposed also on this for comparison.

Application of equalized molar refraction of zeolites and its correlation with the equalized electronegativity and hardness

N. V. K. Dutt, S. J. Kulkarni and Y. V. L. Ravi Kumar

Indian Institute of Chemical Technology, Hyderabad 500 007, India

The equalized molar refraction values for various zeolites have been determined by using Sanderson's equalization concept and atomic refraction (R_D) values. Using Komorowski equation, $\eta = (4\pi\epsilon_0 R_D^{1/3})^{-1}$, hardness (η) and equalized electronegativity (χ) are correlated with the equalized molar refraction (R_m). The average deviation was 5%. From the equalized molar refraction various useful properties like molar polarizability, refractive index, etc. can be determined.

THE applications of equalized electronegativity concept to zeolites and other systems are well-established¹⁻⁴. Based on equalized electronegativity, the charges on oxygen and aluminium were correlated to Si/Al ratio of various zeolites⁵. The water content due to the aluminium fraction was also correlated with equalized electronegativity. We have introduced the concept of equalized chemical hardness of zeolites to correlate various physico-chemical properties⁵. Here we report the concept of equalized molar refraction. The equalized molar refraction is correlated with equalized electronegativity and equalized chemical hardness of various zeolites. Hati and Datta^{6,7} have correlated electronegativity/hardness with

electric dipole polarizability of atoms and clusters.

The electronegativity (ψ) and chemical hardness (η) are defined as

$$\psi = (dE/dN)_z = -\mu \quad (1)$$

$$\eta = \frac{1}{2} (d\mu/dN)_z, \quad (2)$$

where E is the energy, N the number of electrons, μ the electronic chemical potential and z the potential due to the fixed nuclei. The equalized electronegativity is represented as,

$$\psi_{eq} = [N/\Sigma (V/\psi)], \quad (3)$$

where N is total number of atoms and V the number of atoms of a particular element or group. The details are given elsewhere⁵.

Similarly $R_{M(eq)}$, equalized molar refraction is defined as

$$R_{M(eq)} = [N/\Sigma (V/R_D)]. \quad (4)$$

$R_{M(eq)}$, the equalized molar refraction is determined⁸ from atomic refractions (R_D).

As given by Komorowski⁹ the chemical hardness can be correlated with ionic (atomic) refractions by the equation,

$$\eta = (4\pi\epsilon_0 R_D^{1/3})^{-1}, \quad (5)$$

where R_D = ionic (atomic) refraction. Based on this Komorowski equation, we have correlated the equalized molar refraction with equalized chemical hardness and equalized electronegativity separately.

The applications of the equalized electronegativity concept and chemical hardness added to our understanding of various materials and provided new method to determine the properties like charges⁵. This prompted us to understand another fundamental property like atomic refraction through equalization concept. Knowing that the chemical hardness is related to ionic (atomic) refraction, we consider the following equation, on the basis of equation (5)

$$\eta_{eq} = A + (B/R_{M(eq)}^{1/3}), \quad (6)$$

where $R_{M(eq)}$ is the equalized molar refraction.

Using the equation (6), 120 zeolites have been studied with the average per cent deviation of 3.72, and the values of the constants A and B are 13.17 and -4.96 respectively. If we consider ionic refraction values instead of atomic refraction values for exchangeable cations, then the average deviation is 5.11% and the values of the constants, A and B are 0.09 and 5.39 respectively.

Figure 1. R_M equalized molar refraction vs Si/Al ratio.

Figure 2. δ_o , charges of oxygen vs Si/Al ratio.

From equations (1) and (2), substituting in eqn. (6), we get

$$\psi_{eq} = A + B \cdot R_{M(eq)}^{2/3} \quad (7)$$

Using equation (7), for 120 zeolites, the average per cent deviation is 2.67 for atomic refraction with $A=11.81$ and $B=-3.12$. While considering ionic refraction values in determining $R_{M(eq)}$, we have obtained the average deviation 4.08% with $A=7.66$ and $B=-0.5349$. Considering the low (6) per cent deviation and the validity of equations (6) and (7), we can determine polarizability (α) or the extent of the electronic

Figure 3. δ_{Al} , charges on aluminium vs Si/Al ratio.

(chemical) polarization in the unit cell. This extent of polarization (α) in turn can be correlated to the trend in the activity of zeolite in the reaction in general and also the coking tendency.

$R_{M(eq)}$, equalized molar refraction of zeolites against Si/Al ratio is given in Figure 1. $R_{M(eq)}$ decreases with the increase of Si/Al ratio. It is interesting to find that $R_{M(eq)}$ remains almost constant for hydrophobic zeolites, i.e. Si/Al ratio >20 (ref. 12). Further, ψ_{eq} values are derived from $R_{M(eq)}$ using equation (7) and using these ψ_{eq} values δ_o and δ_{Al} charges on oxygen and aluminium respectively were determined. The following equation is used to determine the charges,

$$\delta_o = \frac{\psi_{eq} - \psi_o}{\psi_o} \quad (8)$$

δ_o and δ_{Al} with respect to Si/Al ratio are shown in Figures 2 and 3 respectively. The pattern showed that at the same Si/Al ratio, δ varies, probably, as a function of crystallographic structure and nature of cation. On the other hand, we have reported reasonably linear correlation of δ with respect to $(Al/(Al+Si))$, though it also showed some variation with the structure of zeolites⁵. At this stage, it seems that one should be careful in considering the charges from $R_{M(eq)}$ method.

Thus the concept of equalized molar refraction can be considered and there is scope to derive properties like polarizability based on this $R_{M(eq)}$ concept for a wide variety of materials.

Azadirachtin-induced changes in ecdysteroid titres of *Spodoptera litura* (Fabr.)

C. Mani, B. Subrahmanyam and P. J. Rao

Indian Agricultural Research Institute, New Delhi 110 012, India

Using radioimmunoassay, insect moult hormone (20-hydroxyecdysone) level was monitored in azadirachtin-injected and control larval (final instar) insects of *Spodoptera litura* (Fabr.). Azadirachtin has significantly reduced the hormone level, which suggests its interference in hormonal regulation, growth and development of the insects.

AZADIRACHTIN, a tetranortriterpenoid, has a number of isomers, of which azadirachtin A contributes the bulk. It has varied effects, viz. antifeedant, repellent, growth regulatory, ovicidal and insecticidal properties against many insects^{1–6}.

Studies on physiological effects of azadirachtin showed that it affects the hormonal titre within the insect through tropic factors. The developmental effects of azadirachtin are attributed to a disruption of endocrine events since the azadirachtin molecule itself has a unique resemblance of the major insect steroid hormone, ecdysone⁷. Complete moult inhibition is shown to be due to either a total blockage of haemolymph ecdysteroid or to a delay in the appearance of the last ecdysteroid peak with or without a reduction in peak height and a slow abnormal decline in the peak^{8–11} or the action of azadirachtin as anti-ecdysteroid by blocking the ecdysone-binding sites^{12,13}. Ecdysone production of prothoracic glands incubated in the presence or absence of azadirachtin and/or prothoracic tropic hormone (PTTH) have shown that azadirachtin does not act directly on the prothoracic glands in *Calliphora vicina*, *Bombyx mori* and *Heliothis virescens*^{14,15}. Further studies showed that azadirachtin blocks the release of neurosecretory material from the corpora cardiaca with a reduced turnover seen as a

subsequent accumulation of material within the system¹⁶. Detailed studies on single injected dose of azadirachtin (1 µg/g body weight) into final instar larvae of *Spodoptera litura* have shown deleterious effect on food utilization, midgut enzymes^{17,18}, haemolymph constituents¹⁹, corpora allata volume, median neurosecretion and carry over effects on ovarian development²⁰.

In the moulting process of insects, ecdysteroids [ecdysone and 20-hydroxyecdysone (ecdysterone)] play a vital role. Ecdysterone titre increased with the age of the larvae. Since the azadirachtin treatment affects the growth and development of the insects, it was interesting to know the effect of the same on those important hormones. In this communication, results on the azadirachtin-induced changes on ecdysterone titres of final instar *S. litura* are discussed.

The haemolymph ecdysteroid titres were determined by RIA basically following Borst and O'Connor²¹, Chang and O'Connor²². Ecdysteroid antibody A and azadirachtin A were gifts from Prof. E. Chang, California and Prof. H. Rembold, Max Planck Institute for Biochemistry, Munchen, Germany, respectively. Radiolabelled ligand [³H]ecdysone (50 µCi mmol⁻¹) was purchased from NEN (USA) and scintillation cocktail (Riatron) was from Kontron (Switzerland).

All other reagents [boric acid, bovine serum albumin (BSA) fraction V, sodium chloride, ammonium sulphate and methanol of extra pure quality] were purchased from SISCO Research Laboratory (India).

Azadirachtin was dissolved in 70% ethanol [(ethanol: water) (70:30 v/v)] and injected (@ 1 µg/g body weight) into the newly moulted VI instar larvae of *S. litura*, at the base of one of the I pair of prolegs, using Hamilton^R syringe. Control larvae were injected with 70% ethanol only. The treatments were replicated five times and all the experimental insects were fed with semi-synthetic diet.

Haemolymph samples (40 µl) were drawn at 24 h interval from azadirachtin-treated and control larvae. Samples (40 µl) were collected in clean sample vials and ecdysteroids extracted with 70% methanol: water (70:30 v/v). The mixture was kept at 4°C for overnight to facilitate precipitation and centrifuged at 2,000 g for 10 min in a table top centrifuge. The supernatant was dried in the counting vials at 36°C.

The schematic diagram for the assay is given in Figure 1. Throughout the assay, RIA buffer [containing borate buffer (100 mM; pH 8.5), BSA (0.1%), sodium azide (0.1%) and sodium chloride (0.5%)] was used, unless otherwise stated. The antiserum was diluted in antibody dilution buffer [same as that of RIA buffer except for the high BSA concentration (5%)]. Radiolabelled ligand was diluted in RIA buffer to get 50% antibody binding and 18,000 dpm radioactivity.

The binding of standard or unknown sample (B) was

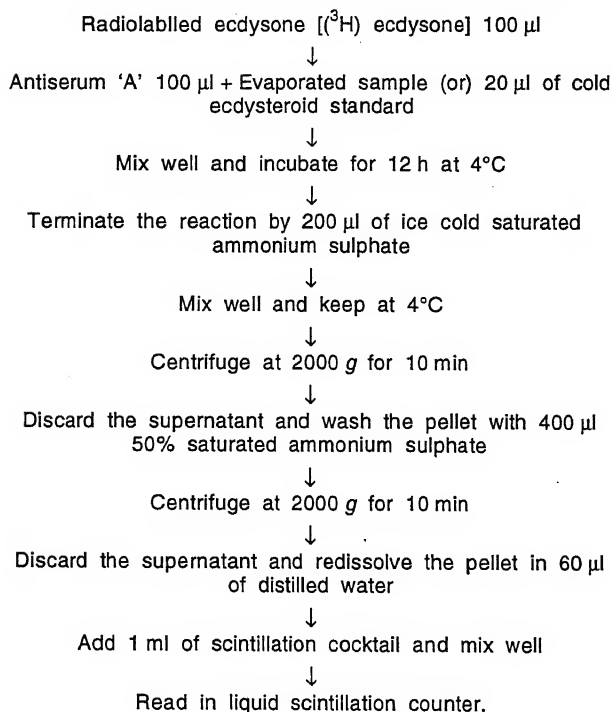

Figure 1. Protocol for the assay.

Table 1. Effect of azadirachtin on 20-ecdysone (ng ml⁻¹) concentration of haemolymph

Hours after treatment	Control	Treatment
24	117.1 ± 5.4	14.7 ± 3.6
48	230.5 ± 14.0	41.2 ± 4.7
72	267.4 ± 19.3	153.7 ± 26.7
96	533.4 ± 43.4	389.9 ± 9.1
120	273.4 ± 12.7	121.7 ± 4.9
Mean	284.5 ± 18.9	144.2 ± 9.8

Comparison by 2-FCRD.

Values are mean (± SE) of five determinations.

CD between main treatment = 16.23.

CD between sub-treatments = 25.67.

CD between main and sub-treatment = 36.28.

expressed as a per cent of maximum binding ($B/B_0 \times 100$). The logit-transformed values were plotted against log-ecdysteroid concentrations (cold ecdysteroid standard – ecdysone and 20-hydroxyecdysone). From the standard curve, the concentration of ecdysterone was estimated by interpolating the values. The titre data were expressed in ng ml⁻¹ 20-hydroxyecdysone equivalents.

The concentration of the hormone at 24 h after moulting into sixth instar was 117.1 ng ml⁻¹ which increased by two folds (230.5 ng ml⁻¹) at 48 h. Azadirachtin treatment dramatically decreased the hormonal level (14.7 ng ml⁻¹) at 24 h. Subsequent increase in the hormonal concentration of the treated larva was similar to that of the normal insects, but with a significantly lower values

(Table 1). Some insects could not complete their life cycle and, both larval (8.7%) and pupal (34%) deformities were observed in the treated insects.

A similar situation was also reported²³ in *S. litura*. The difference between the control and treated in hormonal titres may be due to the effect of azadirachtin on ecdysteroid biosynthesis or its metabolism²⁴.

The haemolymph 20-hydroxyecdysone level remained low during larval feeding and began to increase at the end of the active feeding stage (48 to 72 h) reaching the maximum a day before ecdysis. This is in agreement with the observations on *Plusia aganata*²⁵. It was observed²⁶ that the increase in the haemolymph 20-hydroxyecdysone concentration coincides with the increase in fat body protein level in ligated *S. litura*, suggesting greater synthetic activity of the brain.

The declining hormonal titre in the haemolymph may be due to the greater binding with the peripheral tissues which become physiologically active during this stage, leading to wandering behaviour^{27,28}.

The 20-hydroxyecdysone levels of the haemolymph of the insects reared on semi-synthetic diet are lower compared to those reared on castor leaf²³ which may be due to excessive moisture in the diet causing greater retention by the haemolymph. But the present values are in general agreement with the observations²⁶ on *S. litura* maintained on semi-synthetic diet.

Isozyme polymorphism in diploid and heat shock-induced tetraploid Indian major carp, *Labeo rohita* (Hamilton)

N. Sarangi and A. B. Mandal

Biotechnology Laboratory, Central Agricultural Research Institute, Port Blair 744 101, India

Heat shock-induced tetraploids of *Labeo rohita*, an Indian major carp, were studied for esterase, glucose-6-phosphate dehydrogenase (G6PD) and xanthine dehydrogenase polymorphism involving different tissues. Polymorphic loci were identified in eye lens, kidney and skeletal muscle for G6PD and only in kidney for esterase of tetraploids. In general, intensification of isozyme bands was observed in tetraploids. The polymorphism in G6PD-1 and 2 locus in eye lens, G6PD-2 in kidney and G6PD-1 in skeletal muscle and EST-1 locus in kidney could be used as reliable marker in identifying tetraploid stocks from diploids.

ISOZYMES offer a potentially powerful and reliable tool in resolving genetic relatedness/divergence employing the degree of polymorphism of diverse alleles at different

loci involved in translating specific enzymes and their varied multiple molecular forms, i.e. isomers. They have amply been used as molecular tags in genetic, phylogenetic, taxonomic, evolutionary studies and in strain or type identification^{1–5}.

Enzymes are mostly primary products of transcriptionally active genes and it is assumed that specific enzyme profile is the reflection of the genetic make-up of a given species and may be used as 'finger print' considering all other variables as constant. The present study was aimed at identifying any induced variation due to increased ploidy level (diploid to tetraploid) in three different enzyme profiles across diverse tissues and to assessing the feasibility of employing such altered profile (as marker) in identification of tetraploid fishes. Confirmation of tetraploid status has largely been based on chromosome counting⁶, cellular volume measurement⁷, DNA content⁸ and protein electrophoresis⁹.

Ploidy manipulation was found as a novel approach in altering diverse traits in fish system^{8,10} and promising results in many cases encouraged us to undertake the same with *Labeo rohita* in the Central Agricultural Research Institute, Port Blair during 1993. Thermal shock-induced tetraploid stocks¹¹ were developed and reared under in house hatchery and in natural pond condition for evaluation and characterization. Specimens were collected from the polycraft pool and pond after eight months of rearing. After having tetraploid status confirmed (through chromosomal count following standard technique¹²), liver, kidney, eye lens and skeletal muscle were dissected out immediately on sacrificing the experimental fishes. The cell lysate was prepared in tissue homogenizing buffer¹³. Homogenates were loaded and electrophoresed following standard procedure⁵ in a 5% native PAGE using discontinuous buffer system. Isozymes were detected through specific histochemical staining following Shaw and Prasad¹⁴ for G6PD and Paul *et al.*¹⁵ for esterase (EST) and xanthine dehydrogenase¹⁰ (XDH). The mobility of individual band was calculated through the measurement of R_m values.

The profiles of all the three isozymes are presented in Figures 1–3 along with corresponding zymograms. The allelic expression of G6PD (E.C.1.1.1.49) could be distinctly grouped into two regions in liver and three regions in kidney of tetraploids whereas only two activity zones were found in diploids (Figure 1). The anodal band (locus-3) was a homozygous locus and represented by a single intensely stained band in tetraploids with slow mobility. In diploid, this locus was represented by light-stained band coupled with faster mobility. To the contrary, the presence of an additional zone of activity (locus-2) in the kidney was found to be unique in tetraploids. In the eye lens, G6PD was expressed in three distinct loci (locus-1, 2, 3) of tetraploids (Figure 1, lanes 10 & 11). Three alleles of heterozygous nature

Figure 2. Esterase polymorphism in *L. rohita* (diploid and tetraploid). *a*, photograph; *b*, zymogram. Liver: lanes 1–3 (tetraploid), lane 4 (diploid); kidney: lanes 5–7 (tetraploid), lane 8 (diploid); eye lens: lanes 9–11 (tetraploid), lane 12 (diploid); skeletal muscle: lanes 13–15 (tetraploid), lane 16 (diploid).

characterized by one intensely stained band and two light bands (R_m 0.081–0.1) were found in the cathodic zone. This locus (G6PD-2) was specific to tetraploids. The anodal region, however, in both the diploids and tetraploids was represented by a single intensely stained band with R_m values of 0.298 and 0.317 respectively (Figure 1, lanes 9–11). In skeletal muscle, G6PD was expressed in one locus (locus 3) as a light band encoded by a single homozygous allele in diploids whereas in tetraploids an additional band in locus-1 (R_m values 0.08 and 0.093) having two alleles was expressed.

Information on G6PD polymorphism in fishes is scanty¹⁷. Involvement of one locus in G6PD expression in trout^{18,19} has been reported earlier. Five bands of this isozyme have been observed in the brain and eye tissue of *Heteropneustes fossilis* with identical electrophoretic mobility¹⁶. In the present study, three loci could be identified for G6PD which expressed across different tissues. G6PD activity in the liver, kidney, eye lens and skeletal muscles of *L. rohita* diploids and tetraploids was found variable and distinctly a tissue-specific pattern was observed.

The esterase (E.C.3.1.1.1) activity at different loci in

Figure 3. Xanthine dehydrogenase polymorphism in *L. rohita* (diploid and tetraploid). Liver: lanes 2 & 3 (tetraploid), lane 1 (diploid).

liver is well-recognized with diverse R_m values (0.17–0.84), e.g. five zones in liver, four zones in kidney, two zones in eye lens and three zones in skeletal muscles (Figure 2). Unlike diploids, the esterase activity in liver of tetraploids had five zones with intense staining (R_m 0.18, 0.3–0.43, 0.53, 0.60–0.67 and 0.83). Est-1 was found expressed through two alleles in all except in one specimen. In all the tetraploids, Est-3 was represented by three intensely stained bands and Est-4 (R_m value 0.4) was found to be unique for tetraploids coded by a single allele with high enzyme expression. The anodal Est-5 of these specimens were found to be highly active zones compared to diploids (Figure 2, lanes 1, 2 & 3). In kidney, the enzyme activity which was faintly visible at Est-1 and Est-3 loci of diploids (Figure 3, lane 8) was found to be more or less clearly visible zones (still less active regions) in tetraploids, maybe coded by alleles translating less amount of enzyme activity. The isozyme in eye lens of tetraploids and diploids did not show any variation as represented by light bands at Est-1 and Est-5 (Figure 2, lanes 9–12). In the skeletal muscle, esterase activity was expressed in three loci (Est-1, 3 and 5). The allelic expression in tetraploids was characterized with three alleles and one additional less active region (Figure 2, lanes 14 & 15) at the anodal locus (Est-5). Whereas in diploids extremely low activity was observed at Est-1 and 2 (Figure 3, lane 16).

Esterase in all the tissues of tetraploids was found to

express intensely stained bands when compared to the diploids. In locus-3 and locus-5 of liver and kidney, the activity in tetraploids was well marked, being coded by three and two alleles respectively, whereas the activity was very much low for diploids. The presence of highly active Est-4 in liver and Est-1 in muscle could be the characteristic expression of enzyme in tetraploids.

XDH (E.C.1.1.1.204) was expressed at two loci in both diploids and tetraploids. The intense anodal bands of homozygous nature were clearly marked in all individuals (R_m 0.44, 0.45) but the migration of these bands in tetraploids was comparatively faster. The cathodal XDH-1, characterized with light bands (R_m 0.197–0.296), was heterozygous and less expressive in nature. The activity of XDH-1 locus in diploid specimens (lane 1) was almost negligible in comparison to tetraploids (lanes 2 & 3). The phenotypic expression of XDH with a single intensely stained band in liver corroborated the previous observation²⁰ and the presence of three faintly stained bands in tetraploid liver tissue, reported here for the first time, could be used as a marker in identifying tetraploids.

The present study was undertaken to assess the possibility of using altered isoenzyme profile as a genetic marker in identifying tetraploid fishes. G6PD-1 and G6PD-2 of eye lens (R_m values of 0.081 and 0.096), G6PD-1 of skeletal muscle (R_m values 0.08 and 0.94) and G6PD-2 of kidney (R_m value 0.176) were found as distinct marker bands in tetraploids.

In esterase, more intensely stained bands in different loci of tetraploids perhaps indicative of increased gene dose due to gene duplication¹³ and absence of some less active region, might be an epigenetic modification or post-translational modifications. Similar observations were also reported for malate dehydrogenase in herring¹³. XDH in tetraploids was characterized mostly through fast mobility of the intensely stained single band (locus-2).

Appearance of additional bands in tetraploids as against diploids may be assumed due to gene duplication and thereby enhanced enzyme expression in stainable and detectable quantum which probably could have failed to be stained due to negligible amount in diploids. Formation of heteropolymeric isozyme due to hybridization of protein products of separate loci may be another plausible explanation for development of new bands with entirely different R_m values. It is maintainable that hybrid polymorphs have been reported in many fish species and in polyploid organisms that have undergone extensive gene duplication⁵. The chromosomal duplication achieved through ploidy manipulation was well-expressed in manifesting the structurally polymorphic isozymes in fish.

In conclusion, G6PD-1 and 2 in eye lens, G6PD-1 in skeletal muscle, G6PD-2, Est-1 in kidney, Est-4 and

XDH-1 and 2 in liver could be used as reliable marker with ease and confidence in identifying tetraploid stock of *L. rohita*.

Molecular genetic diversity among soybean plant introductions with resistance to *Heterodera glycines*

A. P. Rao Arelli and D. M. Webb*

Department of Agronomy, University of Missouri, Columbia, MO 65211, USA

*Pioneer Hi-Bred International Inc., Johnston, IA 50130, USA

Contribution from the Missouri Agric. Exp. Stn Journal Series No. 12,435.

Restriction fragment length polymorphisms were used to estimate the genetic diversity among 29 soybean (*Glycine max*) accessions with resistance to cyst nematode (*Heterodera glycines*). Based on the common

marker alleles, both the analyses cluster and principal component have separated the resistant soybean accessions into several groups. Several accessions with known resistance to some races were also found to be resistant to additional nematode races in this research.

In USA, *Heterodera glycines* Ichinohe (soybean cyst nematode) parasitism is a major limiting factor of soybean (*Glycine max* L. Merr.) production. This nematode was first discovered in USA in 1954 and has since been found in 27 states. In 1994 the estimated soybean yield losses were valued at 115 million dollars for 16 southern states¹.

The management of *H. glycines* primarily relies on the use of resistant cultivars of soybean. Most cultivars are resistant to one or two nematode race isolates and the current classification system includes 16 different race isolates². The modern soybean gene pool for resistance is generally regarded to be genetically very narrow, mainly because the introgression of resistance genes from the available sources is restricted to either cv. Peking or PI88788 or both. The narrow genetic base of the resistance sources used in cultivars has been causing shifts in *H. glycines* populations favouring development of more aggressive races and the resistance has not been durable. Use of non-allelic genes, i.e. genes located at different loci for resistance will produce more durable resistance in soybean cultivars.

Presently, 118 soybean accessions are available, which are resistant to *H. glycines*. Some of them were reported to carry non-allelic genes for resistance^{3,4}, but they have not been utilized in breeding programmes, except for a few resistance genes from PI437654 soybean. This line is resistant to race isolates⁵ 1, 2, 3, 5, 6, 9 and 14. Prior knowledge of the genetic relationships among the accessions would facilitate development of resistance genes to improve genetic diversity and gene pyramiding. Traditional techniques do not offer adequate tools for establishing these relationships.

Restriction fragment length polymorphism (RFLP) markers has been widely accepted for genetic analysis and varietal identification by DNA 'fingerprinting'. Genetic relationship on the basis of single-copy RFLP markers has been reported for several crop species^{6,7}, including soybean⁸. All of these investigations pertain to crop cultivars with known pedigrees.

We are not aware of any report in the literature on the evaluation of genetic relationships among soybean accessions with unknown pedigrees having resistance to *H. glycines*. In the study described here, we surveyed 29 resistant accessions and two susceptible cultivars of soybeans using RFLPs to obtain information on their genetic diversity and relationships. A brief summary of this research has been reported in the *Agronomy Abstracts*⁹.

For this study, seeds from 29 soybean accessions with resistance to *H. glycines* were obtained from R. L.

Nelson, Curator, USDA-ARS, Soybean Germplasm Collection. These resistant accessions represent samples from five countries: Argentina, China, Japan, Russia and South Korea. Two susceptible controls, cv. Essex and cv. Hutcheson were also included in the study.

Near-homogeneous populations of *H. glycines* were developed for each of the five races. 1, 2, 3, 5 and 14 based on the methods described previously¹⁰. Bioassays were performed for each of the five races based on the established procedures³. In brief, each soybean seedling was grown in a single polypropylene micropot (200 × 25 mm) filled with steam pasteurized Brosely fine sandy soil. Approximately 20 of these micropots were placed in a 20 cm diameter polypropylene container and maintained at 27 ± 1°C in thermoregulated waterbaths (Forma Scientific Inc., Marietta, OH, USA).

White and light yellow females of a given race of *H. glycines* were chosen selectively and were crushed to release eggs and larvae. Each seedling was inoculated with 1250 ± 25 eggs and larvae using an automatic pipetter (Brewer Automatic Pipetting Machine, Scientific Equipment Products, Baltimore, MD, USA). A total of 40 seedlings were inoculated for each race. The method of inoculation was already described¹¹.

Approximately 30 days after inoculation, plant roots were individually washed with a strong jet of water to dislodge *H. glycines* females and counted under a stereomicroscope. Resistance was determined for each soybean accession and for each of the five races, based on an index of parasitism.

Total genomic DNA was isolated from greenhouse-grown plants of each resistant accession and for each of the two susceptible controls. DNA extracts were obtained according to Keim and Shoemaker¹². Purified DNA was quantified using a Beckman DU-65 spectrophotometer and UV quantitation of DNA method according to Sambrook *et al.*¹³. Samples of genomic DNA were individually digested with restriction endonucleases *Dra*I, *Eco*RI, *Eco*RV, *Hind*III and *Taq*I.

Established procedures were employed for gel electrophoresis, Southern blotting and hybridization with the exception that the hybridizations were conducted using 25–35 ml of hybridization solution at 65°C in glass tubes that were rotating on a rotisserie (Robbins Scientific Corporation, Sunnyvale, CA, USA).

The 32 probes used in the study were primarily single-copy DNA sequences and random clones from a genomic library¹² cloned into the *Pst*I site of the pBS⁺ vector and were transformed into DH5 α strain of *E. coli*. The clones were prepared for radiolabelling by first amplifying the inserts via polymerase chain reaction (PCR) using oligonucleotides of the T₃ and T₇ promoter regions of the phagemid vector pBS⁺ as amplification primers. The amplification was based on the established procedures¹⁴. The PCR amplified inserts were radiola-

belled with ³²P using random priming reactions according to Feinberg and Vogelstein¹⁵.

On a marker basis we have calculated polymorphism index = $1 - \sum p_i^2$, where p is the allele frequency for i alleles 1 to N . On a probe basis, the polymorphic index = $1 - \sum \sum p_{ij}^2$ where different polymorphic loci are summed.

Only the fragments that were polymorphic among accessions and could be clearly scored were used in the data analysis. All bands having equivalent migration distance were given the same letter score. Genetic distances (GD_R) among all possible pairs of accessions were estimated from a modification of Nei's similarity equation¹⁶ as used by Keim *et al.*⁸ in soybean. The proportion of similar RFLP loci, S_{xy} , between pairs of PI lines was estimated as $2N_{xy}/(N_x + N_y)$, where N_{xy} is the number of RFLP loci for which PI lines X and Y possess the same allele, N_x is the number of alleles identified in line X and N_y is the number of alleles identified in line Y. GD_R was calculated as $1 - S_{xy}$. Based on the GD_R matrix (data not presented), a dendrogram was generated to graphically display the calculated distances between genotypes (Figure 1). Cluster diagrams were constructed using the average linkage

Figure 1. Dendrogram of soybean PIs and cultivars obtained from an analysis of 32 probes. Genetic distances calculated from RFLP values were analysed by average-linkage clustering. The scale on the dendrogram represents the degree of divergence.

cluster analysis (Statistical Analysis Systems, Cary, NC) on the distance matrices.

The principal component analysis (PCA) was done by first calculating a correlation matrix among the markers. Eigenvalues and eigenvectors were then obtained from the correlation matrix and these were used to calculate the coordinates of each accession. The accessions were then plotted on the basis of these coordinates (data not presented).

The reaction of PI lines to races of *H. glycines* is reported in Table 1. Results indicate that several PI lines with known resistance to some races were also found to be resistant to additional nematode races (Table 1). For example, PI438489B was resistant to races 3 and 5 and in this study it was found additionally resistant to *H. glycines* races 1, 2 and 14. Of the 32 probes examined, 13 were polymorphic producing two to nine restriction fragment bands. We found that 40% of the probes detected variation among the 29 resistant and two susceptible soybean genotypes.

Both cluster and principal component analyses separated the accessions and cultivars into several groups. Cluster analysis has grouped genotypes based on the

proportion of marker alleles that accessions and cultivars have in common. Genotypes that have a high proportion of alleles in common included 'Peking' and PI339868B; PI437679 and PI84751; PI438342 and PI438496B; and PI437725 and PI438497 (Figure 1). These pairs are distinguishable but very closely related based on the RFLP data.

Based on both the cluster analysis and the principal component analysis (data not shown) most widely used genetic sources for *H. glycines* resistance have 'tight' grouping or clustering. These included Peking, PI88788, PI90763, and PI437654. A few of the resistance genes in both the accessions PI437654 and Peking have been recently mapped using RFLPs^{17,18}. Genetic analyses have indicated that very few non-allelic genes exist among these sources of resistance¹⁹, and their indiscriminate use in cultivar breeding appeared to have contributed to their genetic vulnerability. More virulent race populations of *H. glycines* are being reproduced which continue to infest the resistant cultivars.

Some PI lines with multiple race resistance that were genetically distant from the previously used sources were identified in this study (Table 1). These included

PI438489B, PI404198B, PI438503A, PI89772, PI404166, PI437908, PI209332 and PI437655. The resistance genes in these PIs will be mapped.

The results showed that greater diversity for markers existed among the PIs than the two cultivars used in this study. The two cultivars Essex and Hutcheson were also clustered away from the PIs in the dendrogram (Figure 1). This is expected, because the PIs are in general a diverse group of accessions collected in Asia and South America, whereas the cultivars were derived from a limited number of PIs introduced in USA at the turn of the century. In this study, no relationship was found in general, between geographical origin of PIs and the clusters obtained based on the limited number of probes used, but some degree of relationship was observed for spectrum of resistance. Both PI424595 and PI437908 susceptible to races 3 and 14 which clustered at the lower end of dendrogram have originated from South Korea.

Our study has demonstrated that an analysis of RFLP markers can be used to determine genetic relationships among PI lines of soybean. In the absence of typical pedigree information, DNA fingerprinting should be most useful in establishing their genetic relationship to develop appropriate populations for gene mapping studies.

Aeolian deposition of Arabia and Somalia sediments on the southwestern continental margin of India

Onkar S. Chauhan

Geological Oceanography Division, National Institute of Oceanography, Dona Paula, Goa 403 004, India

Kaolinite, smectite, illite and chlorite as major clay minerals and palygorskite and gibbsite in minor quantities have been recorded from the slope of southwestern continental margin of India. Contribution of kaolinite, smectite and gibbsite is from peninsular India through fluvial discharge. Since formation of palygorskite calls for an arid and hot climate and saline conditions, occurrence of this clay mineral in the sediments of the study area documents aeolian sediment contribution from Arabia and Somalia by the Arabian northwesterly winds.

STUDIES of marine clays are a significant tool to determine sources, sediment dynamics and environment of deposition¹⁻⁴. The climate and geology of the source area³ largely dictates the type of clay species supplied. By and large, characteristic clay minerals of different climatic and geological settings have been identified^{1,3}.

Studies of clay mineral variations in the western continental margin of India mainly suggest two important sources of the clays. Illite and chlorite are reported to be mostly contributed by the Indus River and the low salinity Bay of Bengal Waters (BBW), intruding into the southwestern continental margin during November-January⁵⁻¹¹. Kaolinite, gibbsite and smectite (and minor amounts of illite) are produced due to intense chemical weathering of Indian subcontinent, and are contributed from the adjacent landmass⁵⁻⁷. Two contrasting opinions exist about the dispersal of these clay minerals. Ramaswamy and Nair⁹ have reported a lack of cross-shelf sediment transport and have suggested an along shelf transport of the sediments brought by the major fluvial

RESEARCH COMMUNICATIONS

routes of the Indian subcontinent. Others^{7,12} proposed across-shelf transport of the sediments and clays and suggested the influence of the climate and the geology of the western continental margin of India on local clay mineral distribution. But, aeolian supply from other continents has not yet been documented.

The present work was carried out between Cape Comorin and Quilon (Figure 1). Clay mineral studies of 51 surface sediment samples are the basis of the present study. Sediment contribution by the aeolian processes to the northwestern and the central Arabian Sea, adjacent to Somalia and Arabia, has been documented⁵⁻¹¹. The present work records sediment contribution by the aeolian process to the southwestern continental margin of India.

During the 158th cruise of *R. V. Gageshani*, 51 surface sediment samples along and across 7 transects, spread between 7.0°–9.56°N and 75.35–78.0°E, were collected using a Peterson grab (Figure 1). The samples were washed to remove salts, oven dried at 70°C and were analysed for texture. Pipette separated, < 2 µm, oriented, and air-dried samples were subjected to X-ray diffraction studies on a Philips diffractometer (model PW 1814) using a nickel filtered CuK_α radiation ($\lambda = 1.54$). Standard glycolation methods¹³ were used to aid the identification of expandable clay minerals. Weighted peak area method¹ was used to quantify the clay species. Palygorskite is identified by slow scanning (rate 0.6 2 θ min⁻¹) between 8 and 20° to resolve its principal peaks at 10.4 Å, 6.36 Å and 4.47 Å, and quantified after the method of Sirocko and Lange¹¹. To check the reliability of analysis, about 20% of samples were reanalysed which revealed $\pm 8\%$ accuracy for smectite and $\pm 5\%$ for other clays.

The major clays observed in the study area are kaolinite, smectite, illite and chlorite in the order of abundance (Figure 2). Others present in minor amounts are gibbsite (~5%) and palygorskite (5–8%) (Figure 2). Occurrence of palygorskite (Figure 1) suggests a wide distribution of this clay mineral in the samples. Smectite content (range 42.97–19.94%), generally, shows an offshore-increasing trend (content > 35%), whereas kaolinite content is high (generally 35–40%; at some locations > 40%) along the slope, and off the Karmarna River (Figure 1). Though, on the upper slope illite (15–25%) and chlorite (10–13%) are generally low, along the entire lower slope their contents were found to be higher (illite 25–35% and chlorite > 15%; Figure 1). Gibbsite (~5%) is distributed over the slope region. The results also indicate an absence of < 45 µm size detritus on most of the shelf helping to define a 'no clay zone' (Figure 1).

The climate in the adjacent landmass of the study area is humid tropical – rainfall ranges between 280 and > 400 cm in the inland areas of Western Ghats^{14,15}. The clays reported¹⁶⁻¹⁷ from the soil of the hinterland are

kaolinite and smectite in major quantities with traces of gibbsite. Four small rivers, rising in the Western Ghats (Figure 1) dump their load in this area. The sediments of mud banks and estuarine region (located north of the study area) are reported to have kaolinite and smectite with illite in minor amount¹⁸.

There is a general offshore-increasing trend in the abundance of smectite and kaolinite clays (Figure 1). Owing to the high content of smectite at the southwestern continental margin, Kolla *et al.*⁵ suggested its possible derivation from the Bay of Bengal Waters (BBW). But, illite (80%) and chlorite are the most important constituents of the BBW^{4,19-22}. Smectite too is reported from the adjacent landmass and estuarine sediments^{16,17}, and its content shows more pronounced variations across the slope (< 20% on the upper slope to > 30% in the lower slope) without any reduction in its abundance (~30%) along the slope, particularly in the northerly direction corresponding to the movement of BBW (Figure 1). It is, therefore, suggested that smectite and kaolinite with similar sources and distribution trends, are mainly contributed by the local river discharge and dispersed across-shelf. The presence of gibbsite, forming under humid climate from the weathering in the hinterland³, further corroborates across-shelf transport of the sediment derived from peninsular India. Deposition of illite and chlorite along the southwestern continental margin of India by the low salinity BBW, entering this region

Figure 1. Sampling site, sea bottom physiography and distribution of clays in the sea bed. Note 'No clay zone' in the shelf, and enrichment of kaolinite and smectite on the slope. Distribution of palygorskite in the study area is also shown.

Figure 3. Path of the wind from Arabian peninsula and Somalia.

during November–January^{23–24}, has already been documented¹⁰.

Palygorskite has not been reported from either soil or estuarine sediments though it has been observed over a sizeable area along the slope (Figure 1). Formation

of palygorskite requires saline, semi-arid and hot climate with changes in groundwater level¹¹. Since climate of the hinterland is humid-tropical, formation of palygorskite in this area and its supply from this source appears to be very unlikely. The presence of palygorskite along the slope, therefore calls for a non-local source.

Suitable saline, semi-arid, and hot climate with changing groundwater levels do prevail in the Sebkha and Wadi regions of Arabia¹¹. Palygorskite is also reported from the Mesozoic rocks of the Arabian peninsula and part of Somalia¹¹. In the northwestern and the central Arabian Sea, adjacent to the Arabia and Somalia, content of palygorskite is generally ~10%, which decreases southeasterly and has been attributed to southeasterly dispersal by winds^{5,6,11}.

From Red Sea to Persian Gulf, the Arabian northwesterly winds prevail throughout the year. Aerosol content of these winds is high^{25,26} (3000 µg/m³) and satellite imageries indicate that this dust spreads over the southwest monsoon trajectories in the mid troposphere^{11,27} and its extension has also been observed as far away as south Indian coast²⁸. Palygorskite, besides illite and smectite, is present as one of the significant constituents in the aerosol dust samples^{29,30}. These winds and trajectories of southwest monsoon winds are reported to be the carrier of palygorskite to the northwestern Arabian Sea¹¹. Therefore, in the absence of any local source, and from the foregoing evidences and the satellite data²⁸, it is deduced that the main source of palygorskite lies in Arabia and Somalia. Further, southeastward transport of aerosol dust by Arabian northwesterly winds (as shown in Figure 3) contributes palygorskite to the southwestern continental margins of India.

In the shelf region, a 'no clay zone' has been observed (Figure 1). The prevalent environmental conditions, i.e. high magnitude currents, a large riverine discharge due to heavy rainfall in the catchment areas, and steep river gradient are reported to have inhibited the deposition of the fine silty-clayey particles on the shelf¹⁰. The absence of palygorskite in the shelf, therefore, does not necessarily indicate a weak aerosol source but reflects the role of hydrography which precludes the deposition of fines in the shelf.

Microstructural evidence for the formation of crenulation cleavage in rocks

Manish A. Mamtani and R. V. Karanth

Department of Geology, M.S. University of Baroda, Vadodara 390 002, India

The mica domains of crenulated schists belonging to the Lunavada group of Precambrian rocks in Gujarat show microstructures similar to Schistosité–Cissilament fabric and extensional crenulation cleavage which are features usually developed in rocks from ductile shear zones. While presenting a model illustrating the sequential development of crenulation cleavages and the observed microstructures within cleavage zones, it is suggested that during successive stages of formation of crenulation cleavage, solution transfer is dominant during the earlier stages whereas shearing is important during the later stages.

STRUCTURES such as Schistosité–Cissilament (S–C) fabric and extensional crenulation cleavage (ECC) are commonly known to develop in rocks in ‘ductile shear zones’ (DSZs)^{1–6}. Such structures have also been produced in the laboratory^{7,8}. They form because of a component of extension along a plane of anisotropy². Here we give a description of the microstructures observed in the crenulated schists belonging to the Lunavada Group of Precambrian rocks in Gujarat. These show microstructures along cleavage zones which resemble the structures like S–C fabric and ECC found in DSZs. A model is given to explain their origin during the genesis of crenulation cleavage and the processes operating during different stages of crenulation cleavage development are discussed.

The Lunavada Group of Precambrian rocks occur in the Panchmahal district of Gujarat and parts of southern Rajasthan, India between 22°45′–23°45′ N and 73°15′–74°30′ E (Figure 1). It comprises alternating quartzites and mica schists and belongs to the Aravalli Supergroup^{9–12}. Two episodes of deformation have been reported and the regional metamorphism is dominantly up to the greenschist facies^{10–12}. The rocks are intruded by the Godhra granite. This has resulted in the superimposition of a thermal event over the regional metamorphic event due to heat supplied by the Godhra granite¹³. The present study deals with the microstructures observed in the mica schists.

Mica schists from Vankdi–Vena area lying 18 km east of Lunavada (Figure 1) possess large porphyroblasts of garnet and biotite and show a well developed differentiated crenulation cleavage (S₂). The differentiated crenulation cleavage is formed by microfolding of a pre-existing foliation S₁ and is defined by alternating quartz (Q) and mica (M) domains. Figures 2a, b, e and f show a well-developed differentiated crenulation

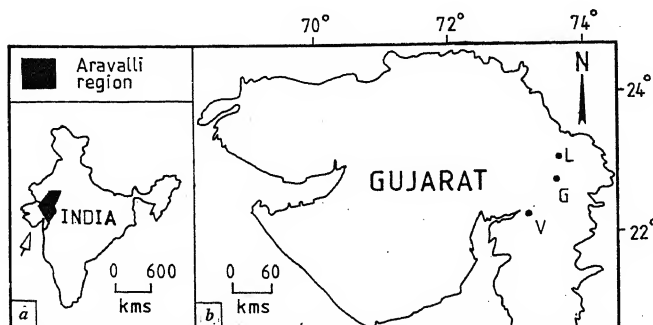

Figure 1. Location map of the study area. Arrow in (a) points to the area shown in (b). L, Lunavada; G, Godhra and V, Vadodra.

cleavage along the limbs of the microfolds. A careful observation of cleavage zones (M domains) has revealed microstructures that resemble those found on the mesoscopic scale in DSZs¹⁻⁶. These are as follows:

- a) In several M domains the S_1 surfaces, defined by mica aggregates, progressively curve sigmoidally and become parallel to the domain boundary (S_2 surface) (Figure 2 a, b, e, f).
- b) In some M domains a cleavage S'_2 develops (Figure 2 c, d, g, h). The important characteristics of S'_2 are: (i) S'_2 forms at a low angle ($<45^\circ$) to the foliation S_2 (domain boundary); (ii) in the domains where it is well developed it imparts a 'button schist' appearance to the M domains; (iii) there is no evidence of metamorphic differentiation during the formation of S'_2 . This suggests that S'_2 defines the real plane of displacement rather than volume loss.

There is a striking resemblance of the microstructures illustrated in the cleavage zones of Figure 2 with those described from mesoscopic scale DSZs. Figure 3 (drawn after Figure 7a of Ghosh⁵) shows the development of S-C fabric in mylonites. Figures 2 a, b, e, f show the progressive sigmoidal curving of S_1 into S_2 which is similar to the S-C fabric found in mylonites illustrated in Figure 3. Similarly, the microstructural features related to S'_2 surface (Figure 2 c, d, g, h) show a resemblance to ECC that have been described in DSZs^{1,2,6}. Significantly, although the mica schists studied here do not belong to a mesoscopic scale mylonite zone or a DSZ, the microstructures observed in the cleavage zones (M domains) of the differentiated crenulation cleavage bear a strong resemblance to the structures found in DSZs¹⁻⁶. This has the important connotation that microstructures resembling S-C fabric and ECC can develop within the M domains of a differentiated crenulation cleavage in mica schists lying outside a mesoscopic mylonite zone. Therefore, it is stated that crenulation cleavage zones can behave as microscale shear zones. During shearing along the cleavage zones, the S_1 , S_2 , and S'_2 surfaces are perhaps similar to S, C and ECC surfaces respectively

— the latter terms have so far been restricted to describe structures in mylonites.

Based on the microstructures observed in Figure 2, the following sequence of events is invoked for the genesis of crenulation cleavage.

Microfolding of the pre-existing foliation S_1 resulted in the initiation of the differentiated crenulation cleavage (S_2). During the initial stages of microfolding (crenulation), solution transfer resulted in the migration of quartz from the limbs of the microfolds to the hinges, whereas the phyllosilicates got concentrated in the limb regions (see Figure 2 a, b, e, f). This led to the formation of domainal fabric in the rock which is characterized by alternating Q and M domains¹⁴⁻²¹. Volume was lost during this process, at least on the scale of a few microfolds, though this is not essential on a larger scale²². After the rock achieved its domainal fabric, the M domains define a zone of strong anisotropy characterized by S_1 mica aggregates. Shearing occurred along the M domains and this resulted in the progressive sigmoidal curving of the micas defining the S_1 foliation within the M domains into parallelism with the S_2 surface, i.e. the domain boundary (Figure 2 a, b, e, f). The microstructure thus formed resembles the S-C fabric of DSZs. Continued shearing along these domains resulted in the formation of S'_2 surface at a low angle ($<45^\circ$) to the S_2 surface within the M domains of the differentiated crenulation cleavage (Figure 2 c, d, g, h). The S_2 - S'_2 relationship is similar to ECC of DSZs. Volume was conserved during the development of S'_2 because metamorphic differentiation on account of solution transfer had already occurred to a large extent during the earlier stages of the formation of crenulation cleavage (S_2).

Figure 4 (modified after Bell and Rubenach²³) shows a model for the sequential development of crenulation cleavages and depicts the microstructures developed at different stages of their genesis. The rock achieves its domainal fabric by stage 3. Solution transfer is the dominant process up to stage 3. Shearing along the M domains becomes significant from stage 4a and results in a structure similar to S-C fabric found in mylonites. Continued shearing along the M domains results in the initiation of an embryonic S'_2 surface in stage 4b and finally a well developed S'_2 surface develops in stage 4c, which is similar to ECC found in mylonites. With further deformation the S'_2 surfaces in M domains totally rotate into parallelism with the domain boundary and the relic crenulations in Q domains are destroyed. This is stage 5 of crenulation cleavage genesis. Finally, in stage 6 the S_2 foliation gets homogenized.

The present study has highlighted the microstructures observed in cleavage zones (M domains) of differentiated crenulation cleavages in mica schists. These cleavage zones develop along limbs of the microfolds and are

Figure 3. Sketch showing S-C fabric that commonly develops in rocks from ductile shear zones (after Figure 7a of Ghosh⁵).

observed to preserve microstructures resembling S-C fabric and ECC, which normally are found in the mesoscopic scale in rocks from mylonite zones or DSZs. The recognition of these microstructures leads to the revival of the question whether crenulation cleavages are pressure solution surfaces or microscale shear zones. Gray²¹ considered all crenulation cleavages as pressure solution surfaces and stated that no appreciable movement occurs 'at any stage' in their development. Interestingly, the present study has revealed that a crenulation cleavage can behave as both a pressure solution surface and a microscale shear zone at different stages of its deve-

Figure 4. Model showing the sequential development of microstructures in M domains during crenulation cleavage development. Solution transfer and resultant metamorphic differentiation dominate up to stage 3. From stage 4a, the domain boundary starts behaving as a shear surface and results in the development of a fabric resembling S-C fabric which occurs in mylonites. With increasing strain and shearing along M domains, an embryonic S'_2 surface initially develops at a low angle to S_2 in stage 4b and subsequently a well developed S'_2 is formed in stage 4c. The S'_2 resembles the ECC found in mylonites. In stage 5 the relic crenulations in Q domains are destroyed and the S'_2 surfaces in M domains rotate into parallelism with domain boundary. In stage 6 the S_2 foliation gets homogenized. Compare stages 4a, 4b and 4c with Figures 2a, b, c and d respectively. The model is modified after Bell and Rubenach²³.

Figure 2a-h. a, b, Photomicrographs showing microstructure in M domains of a differentiated crenulation cleavage in mica schist. The M domains have developed along the limbs of the microfolds. S_1 mica aggregates in M domains sigmoidally curve into parallelism with the S_2 surface. c, Photomicrograph showing a well developed S'_2 surface within the M domains. Note that the angle between S'_2 and S_2 surfaces in (c) and (d) is less than 45° . (e), (f), (g) and (h) are line drawings highlighting the M domains of (a), (b), (c) and (d) respectively. Arrows show sense of shear. Scale bar is 0.05 mm in (a) and 0.1 mm in (b), (c) and (d). Q is quartz grain.

lopment. Pressure solution (solution transfer) is undoubtedly a dominant mechanism during the earlier stages of crenulation (up to stage 3 in Figure 4) and due to this phenomenon the rock attains its domainal fabric characterized by alternate Q and M domains. However, the presence of microstructures resembling S-C fabric and ECC which commonly occur in mylonites, within the cleavage zones (Figure 2) suggests that crenulation cleavages behave as microscale shear zones during the later stages of crenulation, because metamorphic differentiation has already occurred during earlier stages of the formation of crenulation cleavage. This is in accordance with the suggestion of Williams and Schoneveld²⁴ that the S_2 surface becomes the active surface of shear after all the mobile material has been removed from it.

ACKNOWLEDGEMENTS. We thank Prof. S. S. Merh for discussion and suggestions. Comments from two anonymous referees enabled us to upgrade the paper to the present version. Suggestions from Prof. C. W. Passchier (Mainz, Germany) on an earlier version were found useful. The study was supported by the M.S. University Research Scholarship and a field work grant from the A.G.I.D. (Brazil) awarded to M.A.M.

Received 17 April 1996, revised accepted 26 June 1996

Relict coral reef and evidence of Pre-Holocene sea level stand off Mahabalipuram, Bay of Bengal

G. Gaitan Vaz

East Coast Operations-II, Marine Wing, Geological Survey of India, 41, Kirlampudi Layout, Visakhapatnam 530 017, India

A relict coral reef on the outer continental shelf off Mahabalipuram at -115 m depth yielded a radiocarbon (^{14}C) age of 14510 ± 190 yrs BP. A terrace at -130 m depth probably indicates the lowest sea level position during the late Pleistocene. It is inferred that the sea level rose at the rate of 5.71 m/kyr during the early stage of post-glacial transgression between 18,000 and 14,500 yrs BP.

STUDIES document that global sea level has been rising with pauses since the late Pleistocene sea level minimum. Imprints of high and low sea level strands during the late Pleistocene have been well recorded along the west coast of India¹⁻⁴. Although evidences are available about sea level high on the east coast of India⁵⁻⁷, only fragmentary informations about low sea level are available⁸⁻¹³. In this paper, an evidence of Pre-Holocene low strandline from a relict coral reef on the outer continental shelf off Mahabalipuram in the east coast of India has been presented.

Echo sounding (3.5 kHz) data was collected along shore parallel and perpendicular transects on the continental shelf at 10 km interval during R. V. *Samudra Manthan* cruise No. 94. Sediment samples of the mid and outer continental shelf were collected using van Veen grab on 10 km grid. The sediment texture and type were classified. A coral chunk (25 × 20 cm) along with coral debris was collected at -115 m depth (12°33.523'N; 80°37.074'E) off Mahabalipuram (Figure 1). The mineralogy of the coral was determined by X-ray diffraction using CuK_α radiation. The coral was cleaned thoroughly and surface encrustations such as worm tubes and green lichens were removed prior to dating. Radiocarbon age (^{14}C) of the coral was determined by the Birbal Sahni Institute of Palaeobotany, Lucknow.

The continental shelf off Mahabalipuram is about 40 km wide and the shelf break occurs around -135 m depth. Echo sounding profiles (3.5 kHz) reveal the presence of terrace at -100, -110 and -130 m depths, probably related to low strandline positions. Dome-shaped reefal structures occur at about -100 and -115 depths in the outer shelf zone (Figure 2). These features extend parallel to the coast to a limited distance (Figure 1).

The shelf is covered by carbonate-dominated sediments and they are clayey sands with abundant skeletal fragments and ooids and occurs as shore parallel linear patches. Sandy silt and silty clay are also present.

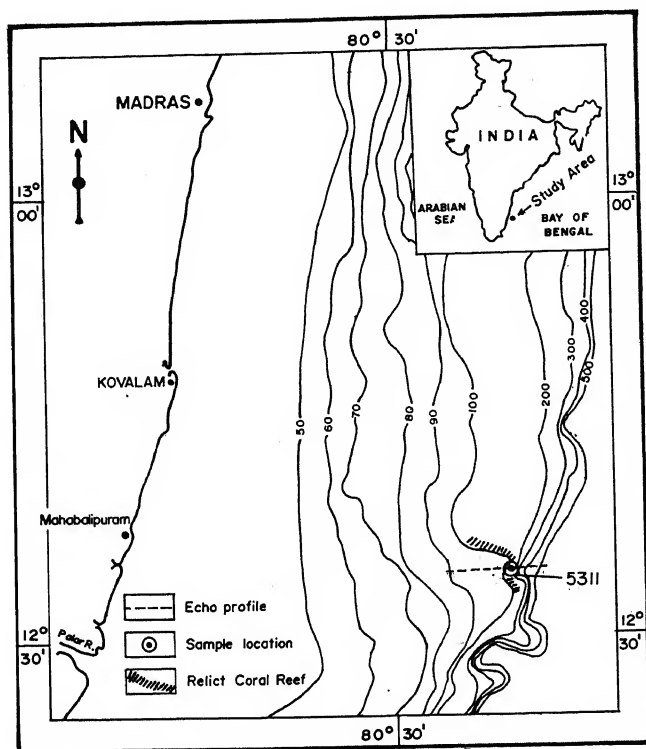

Figure 1. Map showing bathymetry and sample location in the study area.

Figure 2. Echo profile (3.5 kHz) off Mahabalipuram showing relict coral reef (RCR), algal reef (R) and terrace (T).

Calcareous concretions are more common in the outer continental shelf sediments.

The coral chunk recovered from the reef at -115 m water depth is sub-massive, hemispherical and corallites are polygonal to circular (Figure 3). The coral belongs to the genus *Goniastrea* sp. Majority of the coral debris are of branching type belonging to the genus *Acropora* sp. The radiocarbon (^{14}C) dating of the coral (*Goniastrea* sp.) yielded an age of $14,510 \pm 190$ yrs (calibrated) BP.

The X-ray diffraction studies on the coral indicate that it contains only aragonite (100%), thus confirming no recrystallization of aragonite.

Reef-building colonial corals thrive in calm shallow waters¹⁴ with temperature of about 22°C . The presence of patchy coral reef at -115 m depth in the study area

Figure 3. Coral *Goniastrea* sp.

indicates a sea level stand probably at about -110 m depth which facilitated the growth of patchy coral reef at -115 m depth. Further, a lowest terrace feature with ooid concentration was recorded around -130 m depth. This suggests that the lowest sea level during the Last Glacial Maximum (LGM) might have been closer to -130 m in this region. This observation corroborates well with the glacio-eustatic sea level low recorded elsewhere¹⁵⁻¹⁷ at depths between -115 and -130 m.

On the eastern continental shelf of India, terraces at -55 , -60 , -70 , -85 and -100 m depths, probably formed during the Late Pleistocene–Holocene transgression, have been recorded^{9,10-13,18}. Algal barriers at -85 m and -100 m depths off Visakhapatnam have been dated $10,790 \pm 170$ yrs BP and $12,530 \pm 170$ yrs BP respectively¹³. Similarly, the molluscan shells collected from an offshore bar at -17 m depth in Nizampatnam Bay have given an age of 8200 ± 120 yrs BP¹⁰.

It is surmised that the lowest sea level during the LGM was at about -130 m depth in the study area. The coral reef at -115 depth yielded an age of $14,510 \pm 190$ yrs BP. Presuming that the lowest terrace at about -130 m level formed at $18,000$ yrs BP, and there were no pauses in sea level between $18,000$ and $14,500$ yrs BP, it is inferred that the sea level in the study area rose at the rate of 5.71 m/kyr until $14,500$ yrs BP.

Post-Doctoral Research Associateships in Life Sciences and Biotechnology (A DBT-sponsored programme)

Applications are invited from candidates with Ph D in Biological, Chemical or Physical Sciences, or MD, for the award of temporary Research Associateship (maximum duration - 2 years) to carry out research in frontier areas of Biology in the Division of Biological Sciences at IISc under the DBT-sponsored postdoctoral programme. Candidates *who have submitted their theses* (awaiting award of degree) are also eligible to apply, but they may be appointed as Research Associates (Provisional) till they obtain the degree. Minimum consolidated emoluments for Research Associates will be around Rs 4000 p.m. This is an ongoing programme and the PDFs award will be operative from 1 April or 1 October of every year.

Candidates should apply on plain paper giving: (1) Biodata; (2) Summary of Ph D work, including list of publications (reprints if any); (3) Two reference letters from supervisor and persons familiar with their scientific work; and (4) An undertaking that they will continue with the training programme for its duration.

After initial screening, candidates will be called for an interview at IISc., Bangalore in the second week of September 1996/March 1997. The PDF programme will start from 1 October 1996/1 April 1997. Send applications to Prof. K. P. Gopinathan, Chairman, Department of Microbiology and Cell Biology, Indian Institute of Science, Bangalore 560 012 to reach him before 20 August 1996/15 January 1997.

Prof. K. P. Gopinathan
Convener
DBT-PDF Programme at IISc

Resonance — Journal of Science Education. N. Mukunda, Chief Editor. Indian Academy of Sciences, P. B. No. 8005, Bangalore 560 080. 1996.

The advances in science have become intractable and mind boggling in recent times. In India, it is very difficult for a teacher to keep abreast of scientific advances due to a lack of an appropriate journal or magazine. In this context, it is heartening to have *Resonance— Journal of Science Education*, which promises to focus among other things on topics that are difficult to grasp and teach at the undergraduate level. It covers a wide spectrum of sciences. It has an attractive layout with a large marginal space imaginatively used to highlight the important messages. In addition to series, general and feature articles, one finds research news and book reviews dealing with the frontier areas of science. The items in the departments 'Classroom', 'Think it over', and 'Information and announcements' are particularly relevant to the teachers. The character of this journal can be appreciated by a selective reading. A few of these are presented here.

The series on cosmology and geometry are very useful and fascinating with the readers eagerly waiting for the next issue. In both these articles, the authors develop the subject methodically and chronologically emphasizing the evolution of new ideas and concepts. The general article on Fermat's last theorem and the article on prime numbers are very interesting. These are informative both for a beginner and for one looking for recent trends in mathematics.

At present, chemistry is taught to convey only a vast amount of descriptive data. It is here that the series on 'Learning organic chemistry through natural products' and 'Fascinating organic transformations' are very instructive. The feature 'Molecule of the month' describes the chemistry of a novel molecule and surely an eye opener to the state of the art in this area. For example, the discussion on cyclobutadiene in a carcerand, i.e. spheroidal molecular prison is very readable and presented in a simple way. This is an important contribution of the Nobel laureate, Donald J. Cram and co-workers. The series 'Life: com-

plexity and diversity' presents in simple language the exciting facets of biodiversity and will kindle the interest of all the students and teachers of science. The general article 'From matter to life: chemistry?' by the Nobel laureate Jean-Marie Lehn is an inspiring account of his journey into chemistry and it is very appealing to the younger generation. In general, the emphasis in chemistry has so far been mostly on organic chemistry. One hopes that in tune with the current trends of inter-connections in all branches of chemistry, the future issues will dwell upon inorganic, bio-organic and organometallic systems as well. The write-up on the 'Honey bee dance language' is very engrossing and has all the make up of a mystery thriller. Under the feature articles, 'Nature watch' dwells upon the exotic and the unusual aspects of life forms in nature. The themes are very impressive and they are illustrated with attractive photographs as for instance, in the article on bats and their diversity. This section undoubtedly is the most popular part of *Resonance*.

One of the important departments of *Resonance* is the 'Classroom'. Here the teacher gets an opportunity to raise questions encountered in the classroom and having bearings on the syllabus material. For instance, in the classroom, Doppler effect is discussed only in acoustics. Its counterpart in light is not emphasized. In this context, the question pertaining to Doppler effect is relevant for a broader presentation of this subject.

Also, the question on Bose condensation of an ideal Bose gas is intellectually stimulating. The teachers will be eagerly awaiting to see the answers to such questions. This section also provides an opportunity to share with the other members of the teaching community, personal experiences and viewpoints related to the teaching and learning of science. In 'Think it over' one can pose puzzles and paradoxes related to the subjects taught. The problem of the weight of a bird in a cage under different situations is very thought-provoking. It is a good example for highlighting the salient points of Newtonian mechanics, like, Newton's third law, free fall under gravity, hydrodynamic lift and frictional forces.

The section on 'Research news' highlights some significant recent developments in science.

Normally it is difficult to recommend good science books to the library in view of the lack of relevant information on their suitability to teachers and students. In this context review of recent books and reprints of classic books are very helpful.

It is worth mentioning that not all the articles are at the same level of lucidity. Some of them are really difficult to understand. Generally, the presentation of materials under research news is difficult to comprehend. Further, though *Resonance* is termed as a journal of science education, the educational component of the material is generally not found in many of the articles. Only in the presence of such links, one can understand and appreciate fully the subject matter of the articles. By way of a discordant note, one notices some minor irritants in the nature of typos and inadvertent errors. One hopes that the future issues will be free from such blemishes.

We would like to take this opportunity to make a general comment on science education. Invariably, in our schools and colleges excessive emphasis is laid on learning by rote instead of understanding the concepts. Therefore a student who is successful in our examination system does not necessarily possess a grasp of the subject. This calls for a reassessment of our teaching and evaluating procedures. *Resonance* hopefully will act as a catalyst for reforms in science education.

In our view, another journal of this quality and content, does not exist in India. It certainly fills a void in the educational system of our country. Students and teachers stand to gain considerably in the understanding and appreciation of science. The Indian Academy of Sciences has done yeoman service to the community of teachers and students by bringing this out at an easily affordable price. *Resonance* is a valuable reading material to every teacher and is a must in all the college libraries.

BOOK REVIEWS

Annual Review of Earth and Planetary Sciences 1994. Vol. 22. George W. Wetherill, ed. Price: USA \$ 62, elsewhere \$ 67. 691pp; **Annual Review of Earth and Planetary Sciences 1995.** Vol. 23. George W. Wetherill, ed. Annual Reviews Inc., 4139 El Camino Way, P. O. Box 10139, Palo Alto, California, USA. Price: USA \$ 62, elsewhere \$ 67. 513pp.

The recent volumes of *Annual Review of Earth and Planetary Sciences* carry in-depth reviews written by experts in their respective areas of specialization, and present a wide spectrum of research topics, ranging from evolutionary history of whales and dolphins to tectonic and magmatic evolution of Venus. Some of them are currently active topics, while others deal with emerging fields. As Frank Press rightly points out in his introductory article (vol. 23), the golden age which had witnessed extraordinary creativity and discovery may have been over, but the science and its methods will be appropriately remoulded to suit the new age. The articles under review in fact testify to the reshaping of science to suit the demands of a new era.

The volumes reviewed here contain eighteen and fifteen articles respectively on varied topics, with some overlap. The articles, viz. 'The fate of descending slabs' by Thorne Lay (vol. 22) and 'The mechanics of deep earthquakes' by Harry W. Green II and Heidi Houston (vol. 22) deal with similar problems. But the reader is benefitted because of their differences in perspective. The discovery of deep focus earthquakes should be considered as momentous, as they had made some lasting contributions to the earth sciences. Major questions still remain as to the mechanics of the deep earthquakes in the subduction zones, and also what happens to the descending slabs of oceanic crust. Answers to these questions which have implications for mantle convection, are now sought not only from seismology, but also from high pressure mineral and rock physics.

The articles, 'Quantum geophysics' by M. S. T. Bukowski (vol. 22) and 'Effects of phase transitions on mantle convection' by Ulrich Christensen (vol. 23), also address questions related to inner earth environments. The article on

quantum geophysics focuses on the advances made in the theoretical mineral physics, and presents a case as to why the diverse internal properties like structure compressibility, phase transformations, vibrating and optical spectra and rheology that are interrelated at the atomic level, have to be conceptualized and unified from a theoretical point of view of quantum mechanics, especially when the conditions that exist in the inner Earth may be difficult to simulate by the available laboratory techniques. The second paper reviews the role of phase transitions in influencing mantle convection. A larger question, however, is the relative role of mass flux between upper and lower mantle. This is an important problem in earth sciences from another angle. Although the plate tectonics is the accepted paradigm to account for stress accumulation and crustal deformation, it is increasingly realized that the creeping flow of mantle rocks by buoyancy forces due to thermal expansion has a role in generating stresses in the continental crust. The article by Ulrich Christensen presents the results of numerical modelling to resolve the question of nature of mantle convection, and concludes that a compromise of two end member models of whole-mantle convection and layered convection may be plausible.

Palaeoclimatic changes form the theme of many papers in these volumes. 'Late Eocene-Oligocene extinction' by Donald R. Prothero (vol. 22); 'Palaeoclimatic estimates from Tertiary leaf assemblages' by Jack A. Wolfe (vol. 23); 'The initiation of northern hemisphere glaciation' by M. E. Raymo (vol. 22) and 'Sequence stratigraphy' by Nicholas Christie-Blick and Neal W. Driscoll (vol. 23) are the articles under this theme. The first article focuses on the transition from the Eocene to Oligocene Epochs. Improved dating and correlative techniques which increased the resolution of data suggest a protracted pattern of Eocene-Oligocene extinction, precluding any sudden impact events. The review of Tertiary leaf assemblages covers the application of the 'Climate-Leaf Analysis Multivariate Program' (CLAMP) to assess the Tertiary nonmarine climate and its results from some selected areas. This statisti-

cal approach aids in analysing the Tertiary leaf varieties induced by climatic factors. Results show a 'terminal Eocene temperature deterioration' in the continents as well. The fourth article covers the science of sequence stratigraphy. The sequence stratigraphy is relatively a new discipline systematized in the 1970s when Exxon, the oil giant, released its seismic reflection data from the edges of the continents, much to the excitement of scientists world over. From these data, the scientists could decipher the pattern of the rise and fall of sea level over the past 250 million years. These studies have churned out voluminous output in the interpretation of global sea level falls. However, questions remain as to the relative role of tectonic processes and climatic factors (fluctuations in the size of ice sheets) in forcing the coastal onlaps. It is expected that recent Ocean Drilling Program (ODP) in the coastal waters may come up with complementary data. The role of tectonism is emphasized in the article on northern hemisphere glaciation by M. E. Raymo. He examines the climatic transition from warm mid-Pliocene (~3.2 Ma) to the onset of northern hemisphere glaciation around 2.4 Ma. Resolving climatic patterns of the recent geologic past is important, particularly because an increase of 3°C is predicted for the next century.

Among the review articles in the two volumes, one of my favourites is the article titled 'Arc assembly and continental collision in the Neoproterozoic east African orogen: Implications for the consolidation of Gondwanaland' by Robert J. Stern (vol. 22). The impressive style of narration and the brilliant exposition of ideas make it a memorable article. The Neoproterozoic Era (1000–540 my), which encompassed a protracted orogenic cycle, is a fascinating interval characterized by the evolution of eukaryotes and appearance of metazoa, large events of continental glaciation, increased concentration of oxygen in the atmosphere and the development of banded iron formation. Pan-African Orogenic cycle was not restricted to Africa, but throughout the Gondwanaland. The evidences of the Pan-African tectonism indicate that the plate tectonic systems had been in ex-

istence even in the early phases of the Earth's history. The article chronicles the sequence of tectonic events comprising the East African Orogen (EAO). Of special interest is the mention of granulites of southernmost India and Sri Lanka, which were earlier thought to be Archean and Paleoproterozoic, but have since been proved to be Neoproterozoic (660–550 Ma). The author suggests that the younger ages indicate a second younger collision event between the west and east Gondwanic continents. He further states that collision along EAO led to the crustal overthickening and development of strike-slip shear zones and faults related to extensional basin. The modern analogue is the 'escape tectonism' observed in parts of the Himalayan orogen.

Reading this type of compendiums gives you an experience akin to a space mountain ride in Disney World. From a breathless ride in the realm of Neoproterozoic world, we are thrown into a mundane world of earthquakes and active tectonics, and again to much rarefied fields of tectonic evolution of Venus, radar investigations of Mars, Mercury and Titan and physics of zodiacal dust and the mind-shattering enigma of origin of life. I like to focus on the chapter on earthquakes and active tectonics first, being the topics that are closer to my heart. H. Kanamori gives a succinct review of the physical processes of earthquake generation in his article on 'Mechanics of earthquake generation' (vol. 22). There have been significant advances made in the study of slip distribution on a fault. Seismic imaging of major earthquake zones shows that slip models can be interpreted in terms of 'barriers' and 'asperities', ideas to which Kanamori himself has made significant contributions. He emphasizes the mechanical models of faulting involving the factors such as macroscopic and microscopic static stress and dynamic stress fields. The article on 'Active tectonics of the Aegean region' by James Jackson (vol. 22) deals not only with earthquakes, but also tectonics. What is most interesting here is the abundance of observational data, precluding any element of speculation. The whole dynamics of the deformation is built upon from the high quality seismicity data

and measurements of velocity field in the fault zones using space-based geodetic techniques.

Christopher F. Chyba and Gene D. McDonald review some current issues related to origin of life and exobiology research (vol. 23). Consensus is that *sine qua non* of life is liquid water. Thus, search for life is essentially a search for liquid water. This view is criticised as being born out of 'parochialism' by a group led by irrepressible Carl Sagan. An alternate view insists that extraterrestrial life may look quite different from what we are accustomed to. The article also brings out some salient issues concerning the origin of life on Earth. The questions on the sources of energy available to force the prebiotic organic synthesis are also addressed. A 'chicken or egg' problem haunts the researchers in this field. Which formed first: RNA or proteins? The majority favours RNA. On the whole, the authors have done a thorough job and leave out nothing on one of the most engaging areas of interdisciplinary research today.

Some reviews deal with emerging fields. What appeared most exciting to me in this category is an article titled 'Geomorphology and *in-situ* cosmogenic isotopes' by T. E. Cerling and H. Craig (vol. 22). This article presents an avantgarde method to date the geomorphologic surfaces using the production rates of different cosmogenic isotopes. This method of dating the erosional surfaces will help to resolve some of the long-standing problems in geomorphology, archaeology and active tectonics. The work of an Indian scientist, D. Lal finds repeated reference in this paper. Fortunately, a solid infrastructure and a strong tradition exist in our country that is helpful to strengthen and diversify this line of research to solve some specific problems.

The annual reviews also contain articles in the domain of planetary sciences, in particular about radar imaging of Mars and Venus. Other chapters in the volumes cover a potpourri of topics. As no book review is considered in order without a few quibbles, I would like to add that a topical arrangement of articles would have made these volumes more reader-friendly. On balance, I must say that these articles open up wide

vistas of future research, and remind us most emphatically that the earth sciences have really come of age into a world of high quality data, high resolution and increased quantification of natural processes. And, they are recommended to both professionals and students for these reasons.

C. P. RAJENDRAN

*Centre for Earth Science Studies,
P. B. No. 7250, Akkulam,
Trivandrum 695 031, India*

Biology of the Fungi by Dr J. G. Vaidya. Satyajeet Prakashan, I Floor, Sulochan Apartments, Pune 411 038. 1995. I Edition. 670 pp. Price not known.

Fungi have been getting increased recognition as important components of the microbial world and presently global attention is focused on aspects of biology, biochemistry and biotechnology of fungi for enhancing our knowledge base essential for achieving progress. In this context, a book dealing with Biology of Fungi to provide authentic information on the subject is most welcome.

The book on the *Biology of the Fungi* attempts to give an overview of the salient aspects of fungi under two major sections, viz. Fundamentals (Part I) and Fungi in Action (Part II). Topics dealt with under the Fundamentals section include biological characters, vegetative growth and reproduction, ultrastructure and nutritional aspects. In the second part a wide range of topics including fungal pathogenesis, nutrition and metabolism and role of fungi in biodeterioration and biodegradation are covered. Two chapters are also devoted to fungal metabolites and role of fungi in biotechnology.

The author has stated that he has chosen a 'multidisciplinary approach for making fungi comprehensible to the layman' while the references are included for the sake of 'students and research workers'. Each section comprises of six chapters and the contents of each chapter are presented under many subtitles.

While appreciating that the author has expended considerable effort in compiling information pertaining to fungi and presented them in a manner

BOOK REVIEWS

that he has felt optimal for meeting the requirements of his target readership, it appears that for the uninitiated reader, the text is somewhat disorganized to get a comprehensive picture of biology and biotechnology potential of the fungi. For example, the Section I in Chapter 2 deals with heterotrophic carbon nutrition before the aspects of vegetative growth, reproduction and ultrastructure are presented. Nutrition and metabolism including metabolic pathways of carbon utilization are described in Section II. Fungal ecology and distribution (Chapter 8, Section II) should have come in the first section since it cannot be adequately justified to find a place under Fungi in Action. In providing the subtitles and making the descriptions brief or replacing the text with several tabular statements, the author seems to have made it somewhat difficult for gaining a full appreciation of the subject, particularly to the inexperienced student of mycology and fungal biotechnology. There is a paucity of vital information in the text on topics such as fungal biodiversity, selective techniques for pure culture isolation, conservation and identification, genetic

variation in *in vitro* cultures, sporulation, dormancy and mechanism of survival in the natural environment. In the area of genetic engineering involving fungi (page 512), for example, no reference is made to the recent spectacular developments of using filamentous fungi as hosts for heterologous expression of eukaryotic and mammalian proteins like chymosin. That fungi are increasingly becoming preferred hosts in molecular biology due to their efficient protein-secreting potential has also not been mentioned.

In the chapter on Biotechnology, it is surprising that gibberellins are treated under non-industrial products and the description of the whole fermentation is mentioned in just a few lines giving only trivial and insignificant details (page 564). Likewise the description of β -carotene fermentation (page 562) by mucoraceous fungi without detailed mention of the involvement of heterothallic strains and formation of zygospores is a serious omission in a treatise dealing with biology of fungi.

Several additional discrepancies can be listed but it is adequate to state that the text while providing information on

several aspects of fungal metabolism, biochemistry and biotechnology lacks the essential emphasis on those critical aspects which will enable the reader to obtain a comprehensive picture of the biology and biotechnology of fungi. Several errors (e.g. 'hemicellulose is half cellulose molecule' (page 22) and reference to Fig. 2.1 (cellulose) under hemicellulose), spelling mistakes and ambiguous construction of sentences/descriptions (e.g. comparison of fungi and ant colony under social organization (page 11)) also deter the value of the book to a considerable extent. References cited to original papers include many which are not readily accessible to the readers. Perhaps references of relevance to some authoritative reviews on special topics in Annual Reviews etc. would have been more helpful and useful to the readers.

GOVERNMENT OF INDIA
Ministry of Science & Technology
Department of Biotechnology (DBT)

BIOTECHNOLOGY NATIONAL ASSOCIATESHIP SCHEME: 1996-97

Applications are invited from Indian nationals for the award of Biotechnology National Associateship for pursuing advanced research or undergoing specialized training in Indian research institutes/laboratories in the priority areas of Biotechnology, viz. (i) Molecular biology; (ii) rDNA technology; (iii) Immunology and immunodiagnostics; (iv) Animal cell and tissue culture, hybridomas and cell-culture based vaccines; (v) Plant tissue culture; (vi) Animal biotechnology; (vii) Aquaculture and marine biotechnology; (viii) Peptide and nucleic acid chemistry; (ix) Modern techniques in industrial microbiology and bioconversion; (x) Biochemical engineering, downstream processing and bioseparation techniques, computer modelling and process optimization; (xi) Bioinformatics, and (xii) Emerging areas.

The applicants should possess a Ph D/MD degree in areas related to biotechnology. The candidates should hold regular positions in research institutions and should be actively engaged in biotechnological R&D work. Applications from persons working on temporary positions such as research fellows or associates will not be considered. Scientists/technologists belonging to DSIR recognized in-house R&D centres under the aegis of public or private sector units, intending to join public-funded research institutes/national laboratories/universities and vice-versa, i.e. scientists from the latter institutions, joining in-house R&D centres may be given some weightage for the award, provided they propose to work on specific scientific/technological problems relating to the production of Biotechnology products.

Age limit: 40 years; Candidates should have not crossed this age limit as on 1 January 1997.

Details of the award

Duration: Six months to one year. In deserving cases, the duration is extendable by a maximum period of one year. In addition, the Associates who avail the award for a period of nine months or more in India would also be considered for three months training abroad.

Approval for the overseas training (where admissible) will not be automatic and will be decided on the basis of progress made by the Associates in their work within the country under the award, proper justification, and recommendations of his/her Indian supervisor as well as the associates' parent institute. The overseas training can be availed of within two years of completion of the research work/training within the country under the award.

Associates are entitled to (a) monthly associateship of Rs 2500 while in India and US \$ 1200 or its equivalent during the overseas training; (b) disturbance allowance towards housing in India on actual rent basis subject to maximum limit of Rs 500 per month; (c) personal equipment grant of Rs 2000 (lumpsum), provided the Associateship is availed in India for at least six months and, in addition, a personal equipment grant of Rs 2000 for overseas training; (d) Research contingent grant of Rs 10,000 for six months period of the award and then Rs 5000 for every three months, which is disbursed to the host institutes; (e) first class rail fare and air passage cost in economy class for joining host laboratories in India and abroad respectively and back; (f) the Associates availing the award in another institute located at the same station of the host institute will not get the monthly associateship and disturbance allowance, except the personal equipment grant and research contingency grant.

The selected candidates shall be entitled to the payment of salary and other service benefits by the institutions to which they belong. However, no liability on any of this account will be borne by DBT.

Every selected candidate shall be required to execute a service bond to serve in India for at least one year after completing their training under the award, but in case of the overseas training, the bond's period will be two years and the bond is to be executed in supersession of the earlier bond.

Selected candidates should commence work under the award before 31 December 1996.

Candidates should submit their applications typed on plain paper (six copies with single enclosures) in the format given below. No advance copy will be entertained. Candidates should ensure that application through proper channel should reach Shri R. N. Mehrotra, Director, Department of Biotechnology, Block 2, CGO Complex, Lodhi Road, New Delhi 110 003 by 15 September 1996. After completion of selection procedure results of selection will be communicated during December, 1996.

FORMAT

Application for the Biotechnology National Associateship (199-97)

(1) Applicant's name (in full), designation and address (2) Father's/husband's name (3) Date and place of birth and age (4) Academic qualifications (degree onwards with subjects of specialization and distinction(s), if any) (5) Past and present employment record (give details about employer(s), position(s) held and its nature - temporary/permanent, duration, duties and pay in chronological order) (6) Subject of current research work (enclose details of the research work being pursued by the candidate) (7) No. of research publications during the last five years (enclose list and attach reprints of three research papers which you consider the best) (8) Proposed subject of research/training (enclose (i) the precise research/training programme to be undertaken during the award, (ii) its relevance to the priority areas identified by DBT, (iii) to the plans and programmes of the parent institute, and (iv) candidate's future research plan for utilizing the knowledge gained during the award) (9) Proposed place of research/training (has the consent of host-institution been obtained?, if so, attach the consent letter) (10) Period for which the associateship be availed (11) Duration and other details of the past overseas visits, if any (12) To which DBT identified priority area, the proposed research/training programme belongs.

Place

Date

Signature of the Candidate

STATEMENT FROM THE PRESENT EMPLOYER

(As per the terms and conditions of the associateship, candidates selected for the awards should be granted deputation terms such as entitlement to the payment of full salary and continuation of other service benefits during the period of the associateship by their employers. The parent institutions/employers must indicate clearly their commitment to this effect as also about continuity of employment after the associateship period. Applications which are forwarded without such statement may not be considered. Whether the candidate is on regular or permanent staff of the institutions must also be indicated in the statement.

NOTE: (1) The Associateship is tenable only at those institutions which are engaged in major biotechnological research programmes. The DBT has identified the following list of such institutions: BARC, TIFR, HLRC, CRI, IIT, Haffkins Institute, Bombay; AIIMS, JNU, DU, CFB, IARI, IIT, NII, Delhi; NCL, NIV, HAL, Poona University, NFATCC, Pune; IICB, Bose Institute, Jadavpur University, Calcutta; IVRI, Izatnagar; IISc, Bangalore; Anna University, IIT, Madras; IIT, Kharagpur; CCMB, Hyderabad; IMT, Chandigarh; CFTRI, Mysore; CRI, Kasauli; RRL, Jammu; CDRI, NBRI, CIMAP, Lucknow; MKU, Madurai; BHU, Varanasi; MSU, Baroda; Roorkee University. However, other institutions having well-established lab facilities and working actively in areas of biotechnology may also be considered in this regard. Candidates should correspond themselves with their host-institutes for their placement. (2) The Associateship is not tenable at the candidate's parent institutes. (3) Applications not sponsored by employer and forwarded by the institution/organization or received after the last date are likely to be rejected.

INDIAN INSTITUTE OF SCIENCE

BANGALORE 560 012

INVITES applications for **SCIENTIFIC OFFICER GR-II**– 2 posts (1 reserved for SC and 1 General) in the Central Cryogenic Facility in the scale of Rs 2200–75–2800–100–4000.

QUALIFICATIONS AND EXPERIENCE

Essential:

Post No.1. (Reserved for SC): M E/M Tech/M Sc (Engg.) in Mechanical/ Electrical/ Electronics/Cryogenic Engineering/Industrial Production with a bachelor's degree in Engineering.

Post No.2. (General): First Class in M E/M Tech/M Sc(Engg.) in Mechanical/ Electrical/Electronics/Cryogenic Engineering/Industrial Production with a bachelor's degree in Engineering.

Desirable:

Exposure to a cryogenic laboratory/industry, especially in the operation and maintenance of liquid nitrogen, liquid helium plants and refrigeration plants. Experience of working in cryogenic research projects will be given due weightage.

Job Description:

The selected candidate is required to take responsibility in the operation and maintenance of cryogenic plants and to actively participate in the various R&D projects taken up in the Facility and is also expected to carry out any other duty assigned from time to time.

For application forms and detailed information, please write to REGISTRAR (Unit IA) together with an IPO for Rs 10/- drawn in favour of Registrar, IISc. (free of cost to SC/ ST candidates on production of Caste/Tribe Certificate) along with a self-addressed stamped (Rs 2/-) envelope of size 28 × 18 cm on or before 23 September 1996.

For further information please contact by e-mail at the address: office@ccf.iisc.ernet.in.

Last date for receipt of filled in application form is 4 October 1996.

Plants as communicators

It was many decades ago that J. C. Bose attempted to frustratingly educate the reluctant biologists and in particular the conservative botanists about the ways in which plants could feel, respond and even communicate. What he earned to begin with, was mostly ridicule. Gradually, however, the reluctance gave way to curiosity, and the ridicule was replaced by sympathy if not apology. The conservative view that plants are different from animals did erode and they were viewed just as a continuum in the spectra of living things created and shaped by the Darwinian forces of natural and sexual selection. There are a lot more botanists today who are willing to accept plant ethology as a field with strong conceptual basis and without the stigma of anthropocentric views; it has been realized that these sessile organisms could in fact feel, respond and communicate in their own way. For instance, plants attacked by the defoliating insects are known to emit volatile chemicals which induce other plants in the neighbourhood to synthesize the antifeedants in order to deter the defoliators – a kind of warning process where the potential victims are signalled against the impending dangers of defoliation.

Interestingly, certain defoliating insects themselves seem aware of such strategies of the plants much more than some botanists are willing to accept that plants could indeed do so. It has been shown that certain cucurbits when attacked by the defoliating insects send the signal from the parts that are fed upon (leaves) to other parts of the plants from where the antifeedants are synthesized and translocated to the part of infestation (leaf) such that further damage by the pest is minimized. However some defoliators are known to first girdle the petiole of the leaf before they start feeding such that the antifeedants from other parts of the plant do not reach the target leaf. Consequently, the insect could de-

vour the whole leaf without any defence by the plant.

One interesting question that obviously emerges is how fast and how does the plant feel the defoliation by the insect and how is the signal transferred to other parts of the plant. Sashidhar and his colleagues at the University of Agricultural Sciences, Bangalore and Sinha and his group at Indian Agricultural Research Institute, New Delhi (Sinha is now in the Water Technology Centre, IARI) have been investigating exactly such details of signal transfer within the plants in a different context – they are studying the mechanism of signal transfer under conditions of drought stress to the plants. Sashidhar's group is evaluating the possibility of abscisic acid (ABA) as a signal emerging from roots subjected to moisture stress while Sinha's group is tracking the electric pulses as potential signals between stressed roots and leaves above ground.

Consider a plant experiencing the moisture stress. It is very essential that the plant shifts its physiology from a highly metabolic state towards a state that conserves its water while maintaining the minimal life processes. This shift requires that the stress experienced by the roots below the ground is conveyed to the leaves above the ground. These signals help the leaves close their stomata to minimize the transpiration through which much of the water loss occurs in leaves. Such message transfer has to occur as rapidly as possible such that not only could the plants minimize their metabolic activity following the moisture stress, but also resume their normal physiological activity following water loss. Further the signal transferred should also carry the information regarding the extent of the moisture stress in order that the response of the leaves is in proportion to the severity of the stress. Rekha and others from the Sashidhar group at University of Agricultural Sciences, Bangalore, review (page 284) the merits and constraints associated with the ABA and electric pulses as

signals in such processes. They narrate the difficulties of creating the moisture stress as a single signal-emitting process in such studies. It is not unlikely that the groups might look for other stresses such as defoliation of leaves in species such as cucurbits where probably the induction of signals could be much more sharp. In any case their study is one step further towards viewing plants not different from animals in their skills of communication and behaviour.

K. N. Ganeshaiah

Solvent effects

Most chemical reactions are carried out in solution, with solid state and gas phase reactions being practised by only a small population of chemists. While considerable attention is usually paid to the structures and stabilities of reactants and products, the subtleties of the solvent medium are usually conveniently ignored. At times clever manipulation of solvents can result in dramatic enhancements of reaction rates and product yields.

A notable example is the use of aqueous solutions to carry out Diels-Alder reactions. In water, salt effects can be striking. For example in the synthesis of the natural product cantharidin ultra high pressures (16–18 kbar) were found to be necessary. The use of lithium perchlorate in diethyl ether results in efficient synthesis at atmospheric pressure. Can such solvent effects be rationalized? Anil Kumar (page 289) reviews studies that suggest that 'internal pressure' of a salt-solvent system can serve as a measure of the electrostriction effect. Taken together with activation volumes for reactions, this quantity affords insights into the causes of the observed rate accelerations. The author extends these ideas to an apparently unrelated, but interesting problem – the thermal stabilities of DNA

duplexes. Spectacular changes in melting temperatures of double helical DNA occur in the presence of salts. The treatment of these solvent effects discussed in the article by Anil Kumar departs significantly from conventional wisdom. Rational 'solvent engineering' to control reaction rates, stereoselectivities and thermal stabilities may indeed be possible in the not-too-distant future.

P. Balaram

Visibly spectacular pressure-induced transitions in copper metagermanate

Copper metagermanate (CuGeO_3) is a very soft layer-type material like mica with a light blue colour and crystallizes in the orthorhombic space group Pbmm (C_{2h}^2). The discovery of spin-Peierls transition below 14 K at ambient pressure by Hase, Terasaki and Uchinokura (*Phys. Rev. Lett.*, 1993, **70**, 3651) has generated considerable interest in this system. It is of interest to note that CuGeO_3 is the first inorganic system to exhibit the exotic spin-Peierls transition when cooled to low temperatures.

Recent high pressure investigations by Jayaraman and co-workers at the University of Hawaii (*Phys. Rev. Lett.*, 1995, **75**, 2356; page 306, this issue) have shown that this system exhibits several pressure-induced phase transitions. The novel aspect of the high pressure behaviour is the spectacular colour changes associated with these phase transitions. These authors have carried out extensive high-pressure investigations on this system using Laser Raman Spectroscopy and optical microscopy as diagnostic tools in the conventional diamond anvil pressure apparatus. Three distinct high-pressure phases are observed in the

7–9 GPa (70–90 kbar) region when the normal orthorhombic phase (phase I) of CuGeO_3 is compressed. However, the type of phase obtained depends sensitively on the hydrostaticity of the pressure transmitter employed in the studies. Thus when a gas like helium or a liquid like 4:1 methanol/ethanol mixture is used as a pressure transmitter (which ensures a near hydrostatic pressure environment for the sample), the sample as observed by an optical microscope contracts abruptly by nearly 15% in the b -direction near 7 GPa. This new high pressure phase labelled phase II with a striking contraction in the b -axis direction has a pale green colour and a Raman spectrum different from that observed in phase I. The reverse phase transition occurs near 5.6 GPa on pressure release. It is to be emphasized that helium has been established to be a perfect hydrostatic medium up to 11.8 GPa at room temperature and methanol (which freezes just a little above 7 GPa) provides a similar environment for the sample.

The usage of argon which freezes at a relatively low pressure of 1.2 GPa at room temperature leads to a rather complex behaviour. The normal orthorhombic phase (phase I) on pressurization turns blue near 7.5 GPa (designated as phase III). Even as this transition is progressing, these authors observed yet another phase transition (phase IV) accompanied by a colour change from blue to green. It may be remarked that each of these phases has a characteristic Raman spectrum. The green phase (phase IV) which is stable up to 15 GPa reverts to the blue phase (phase III) near 5 GPa on pressure release and further can be quenched to ambient pressure. The quenched phase transforms to the original orthorhombic phase only on heating to 600°C.

These visibly spectacular pressure-induced phase transitions with a

rich variety of phases in a non-hydrostatic pressure environment pose several interesting possibilities. The authors point out that the structure of copper metagermanate is closely related to the pyroxene family minerals but with an important difference. The backbone structures consisting of corner shared GeO_4 tetrahedra in this system lie on the same side of the chain while they lie on either side in a pyroxene chain. The stability of this chain is rather low because of the strong repulsion of the highly charged Ge^{4+} ions. This consideration has prompted the authors to propose that this delicately balanced chain structure transforms to the stable pyroxene type of structure at high pressures. Although the structures of these high pressure phases have not yet been determined, the blue phase is speculated to have the pyroxene type of chain structure. Since the blue phase can be pressure quenched, structural work on these samples would confirm or otherwise this conjecture.

The observation of the pale green phase (phase II) in truly hydrostatic media is perhaps the most interesting aspect of this work. Raman spectra of this phase seem to confirm that the chain structure is preserved during the phase transition. The abrupt decrease in the b -axis accompanying the transition is possibly related to a rotation of the chain in the structure without breaking any bonds. The transition from phase I to phase II is observed only when the sample is unconstrained (true hydrostatic medium) while the transition proceeds in a complex way when the sample is constrained in the non-hydrostatic pressure medium. The authors speculate that the phase II is a ferroelectric-ferroelastic phase. Further work on this system should throw more light on these fascinating possibilities.

CORRESPONDENCE

Patterns of creativity in arts and sciences

This refers to the lecture entitled 'Shakespeare, Newton and Beethoven or patterns of creativity' by S. Chandrasekhar (reprinted in *Curr. Sci.*, 1996, **70**, 810). About the contrast in the patterns, Chandrasekhar remarks, '... two facts emerge with startling clarity: the remarkable similarity in the creative patterns of Shakespeare and Beethoven on the one hand, and their stark contrast with that of Newton on the other.' At the age of forty-seven Beethoven said, 'Now I know how to compose.' Chandrasekhar writes 'And this to my mind is the center and the core of the difference: the apparent inability of a scientist to continually grow and mature.' In another article, 'Beauty and the quest for beauty in science' (*Phys. Today*, July, 1979) Chandrasekhar makes his point clearer. An artist '... ascent to higher peaks of accomplishment. But I am not aware of a single instance of a scientist of whom the same can be said. His early successes are often his last successes.'

Chandrasekhar has mentioned only one feature in which a sharp contrast

exists. We point out a few more, in which we find equally striking contrast.

All artistic creations have some form of perfection associated with them. The slightest modifications impair their beauty. Nobody can produce an improved version of Shakespeare's play or Beethoven's symphony. But a scientific theory grows continuously from the contribution of other scientists.

Original works of arts do not lose their beauty with time. People read and enjoy Shakespeare's plays even today. On the other hand original works of science gather dust on the shelves.

The ecstatic joy that a scientist experiences when he discovers a new fact or a new pattern or symmetry in nature, is often compared to the aesthetic feeling generated by a work of art. But there is a striking difference. When the new discovery becomes a part of the scientific knowledge, it loses the capacity to excite mind in the same way. Only the discoverer seems to have the privilege. But a work of art continues to trigger sensitive minds to ecstatic rapture long after it was first created.

Discovery of surprising new facts may excite the mind to ecstasy. But nobody, I believe, would credit an experimental discovery as having aesthetic elements. On the other hand, Einstein's general theory of relativity is almost universally acclaimed as endowed with exceptional aesthetic qualities. This is, however, not true for all theories. About quantum mechanics Gellman remarked, 'Quantum mechanics – that mysterious, confusing discipline which none of us really understands but which we know how to use'. We wish to conclude by putting a small question mark after Chandrasekhar's emphatic statement '... in the arts as in sciences, the quest is after the same elusive quality: beauty.'

SCIENTIFIC CORRESPONDENCE

The Pipliya meteor shower: A preliminary study

The meteorite which was seen to fall on 20 June 1996 at 2030 hours by local residents at village Pipliya Kalan (lat.

26°2'5" long. 73°56'30"), Pali, Rajasthan, India has been studied preliminarily and hereby named as the

Pipliya meteorite. The present report is the first technical note on the meteorite. The location of the fall

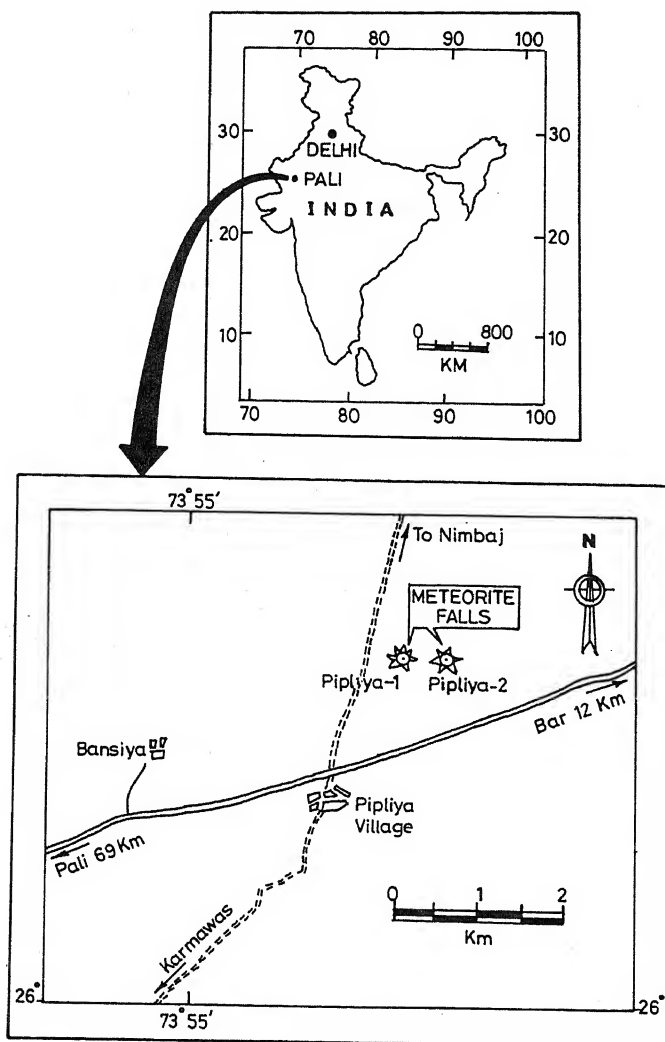

Figure 1. Location map: Meteorite fall on 20 June 1996 near village Pipliya Kalan, Dist. Pali, Rajasthan.

of the Pipliya meteorites is shown in Figure 1.

The two meteorites of the same meteor shower are hereby named as the Pipliya-1 and the Pipliya-2. The Pipliya-1 meteorite, approximately weighing 20 kg, was broken into many smaller pieces by Prabhu Lal Seervi. Nearly 15 kg of the pieces were recovered from him by the authorities of the Department of Mines and Geology, Government of Rajasthan. Another meteorite of the shower, weighing nearly 10 kg, was recovered by us 500 m away from the site of fall of the Pipliya-1. As meteorites could have a special distribution pattern from a meteor shower¹, we are intensively scaling nearly a 20 sq km area around Pipliya Kalan

following the local villagers' version that six fragments have fallen. This leaves four fragments yet to be recovered.

The crater formed due to the impact of Pipliya-1 is 50 cm deep and 70 cm in diameter. The splash reached up to 5 m away from the crater. There was no visible sign of scorching on a 10 m high tree, three metres away from the crater. The crater formed due to the impact of the Pipliya-2 is 40 cm deep and 50 cm in diameter. Both the craters are very small in size compared to the size of the meteorites. The cultivated soil in which craters were formed was wet and muddy due to rains. The meteorites and the craters are shown in Figure 2.

The Pipliya-2 has a glossy pitch black crust of nearly 500 μm thickness. The same type of crust is seen on different pieces of the Pipliya-1. The crust has no fissures but has thumb marks and knobs (Figure 2a) known in the meteorites². Megascopically, both the Pipliya-1 and the Pipliya-2 under the fused crust, are typical stony meteorites, gray to whitish gray in colour, coarse to fine grained in texture, friable and highly shattered in nature. Megascopically, both consist of two types of rocks welded together, hereafter referred to as type A and type B. Type A is a fine-grained gray coloured rock while type B is a coarse-grained, grayish white coloured rock with a very thin black welded boundary between the two types. Type A and type B are distinct microscopically both under ordinary light (Figure 3a) and crossed nicols (Figure 3b). The rock as a whole is a complex breccia consisting of fragments which are generally angular but sometimes rounded. The boundary of the fragments is dark gray in colour.

The study of thin sections under petrological microscope reveals that type A is composed of grains of pyroxene (65%), plagioclase (25%), opaque minerals (6%) and some xenoliths (4%). Type B is composed of pyroxenes (55%), plagioclase (40%) and opaque minerals (5%). Pyroxene is mostly clinopyroxene of pale pink colour, non-pleochroic, with moderate extinction angles. Some grains show twinning (Figure 3d) while some others show banding which may be exsolution lamellae. Plagioclase occur as euhedral to subhedral laths which are more elongated in type B. It is mostly bytownite as determined by Michel-Levy's method. Twinning is very complex in some grains. It shows twinning according to Carlsbad law either alone or combined with albite twinning and pericline twinning (Figure 3d). Opaque minerals could be magnetite as triangular, square or rhomb shaped sections are present which could be yielded by octahedral crystals of magnetite. Thin edges of these grains are neither brown or translucent nor white or yellow, which rules out the possibility that they may be chromite and ilmenite, respectively. (Note the limitations of the thin section study.) Type B shows equigranular and intergranular textures (Figure 3c), with minerals showing extreme shock effects:

Figure 2 *a-d*. *a*, The Pipliya-2 meteorite; *b*, Crater formed by the Pipliya-2 meteorite; *c*, Pieces of the Pipliya-1 meteorite; *d*, Crater formed by the Pipliya-1 meteorite.

Figure 3 *a,b*. The Pipliya-1 meteorite under microscope showing type A and type B rock types (also indicated as A and B). The black line demarcates the boundary between the two. Pyroxene inclusions are present in type B. *a*, Ordinary light $\times 40$; *b*, Nicols crossed $\times 40$; *c*, Type B rock under microscope showing intergranular texture. Note fractures and displaced lamellae in plagioclase laths. (Nicols crossed $\times 40$); *d*, Plagioclase crystal showing twinning; under Carlsbad law, albite twinning and pericline twinning. (Nicols crossed $\times 100$).

Figure 4 *a, b*. A plagioclase crystal showing prominent shock features under polarized light (*a*), and under crossed nicols (*b*) (both $\times 40$); *c*, A pyroxene crystal showing twinning under Carlsbad law. (Nicols crossed $\times 40$). *d*, Xenolith in type A, showing microcrystalline, equigranular texture. (Nicols crossed $\times 40$); *e*, Xenolith consisting of opaque mass showing pyroxene inclusions. (Nicols crossed $\times 40$); *f*, Xenolith showing granular pyroxene filling the spaces between the plagioclase laths. (Nicols crossed $\times 40$).

strain shadows, shattering, cloudy appearance, fractured and displaced lamellae, undulose extinction, etc. (Figures 3c, d and 4b). Type A shows subophitic to ophitic texture. Type A rock also shows some other fragments looking like xenoliths. One xenolith shows microcrystalline equigranular structure (Figure 4d), another encloses few pyroxene grains in a thick opaque background (Figure 4e). The third xenolith consists of granular pyroxene filling the

spaces between the rosettes of laths of plagioclase (Figure 4f).

The specific gravity of one of the pieces of the Pipliya-1 meteorite is 2.78 (mercury displacement method). There is no perceptible radioactivity as detected by scintillometer in any fragment of the meteorites.

The expanding world of 2-acetyl-1-pyrroline

2-Acetyl-1-pyrroline (2AP) was first reported in 1982 as the principal component of the pleasant aroma of fragrant varieties of rice¹. Such a common source of fragrance was discovered so late, probably because of the unstable nature of the molecule and the general fact that even the comparatively blunt human nose is more sensitive than the sophisticated instruments of analytical chemistry.

Unexpected newer sources of 2AP are now being revealed. I first followed the trail of this elusive molecule (Figure 1) thirty-odd years ago when George Schaller had undertaken the first long-term study of the tiger and brought to the notice of scientists the musky, milky fluid sprayed upwards by tigers and tigresses, presumably to leave communicatory signals². With Schaller I noticed at Kanha, Central India, the smelly signal of a tiger, uncontaminated by the polluting odour of unclean zoos. In 1976 I had the opportunity of closely studying the fluid of a pet tigress and the odour of fresh sprayings seemed to be surprisingly similar to the aroma of

basmati and other fragrant rice (Figures 2, 3). Since then my colleagues and I have been studying the tiger fluid and we have established that the volatile smelly molecules are a number of amines, aldehydes, free fatty acids, etc., but the most elusive of them is a molecule similar to 2AP (refs. 3-7). Rice aroma and tiger aroma turned out to be identical in the course of investigations utilizing paper chromatography and gas-liquid chromatography but for lack of 'sniff GLC' (where one part of the test material is led to the flame ionization detector and the other, to the nose for sniffing) the latter set of experiments was not conclusive. Further confirma-

tion has now been obtained as described below.

Synthesis

Following the initial attempt of Buttery *et al.*¹, Schieberle⁸ succeeded in finding a simple method for synthesizing 2AP. Proline and a sugar (sucrose, fructose or glucose) form 2AP at 170°C. In our hands the procedure led to the production of two different fragrant substances S_1 and S_2 . S_2 seemed to be identical to the tiger aroma and rice aroma⁷. At first we had the impression that S_1 , the major component, was 2AP (ref. 7) but recently by

Figure 1. Structure of 2AP.

Figure 2. The raised tail of a tiger indicates that it is ready to spray a fluid containing 2AP.

Figure 3. Rice – A source of 2AP.

comparing authentic synthetic 2AP from Schieberle's laboratory we have established that S_2 of our first synthesis, rice aroma, tiger aroma and 2AP are identical as established by paper chromatography and GLC (squalane column).

In another synthesis we succeeded in obtaining a large amount of S_2 (2AP) but under the anhydrous conditions of Schieberle⁸ we usually obtained variable results. A slight modification using an aqueous solution of proline and sugar led to more uniform production of 2AP (ref. 9). The temperature of the solution inside the container was later measured and found to be between 105°C and 110°C. The temperature range for 2AP production is narrow; 2AP is not formed even at 103°C, but at 105°C the first whiff of the pleasant aroma is unmistakable.

As the quality of aroma in compounds like carvone and limonene is known to depend on the chirality of the molecule, we synthesized 2AP with both L-proline and D-proline. The quality of 2AP-aroma turned out to be independent of the chirality of proline.

Sources of '2AP-like aroma'

Fragrant rice, tiger and leopard produce this aroma which is absent in the African lion and almost absent in a cheetah I studied in Namibia. People in both England and India have described rice aroma as mousey. It is worth investigating whether certain strains of mice at certain times produce this odour. I have also smelt this fragrance in a certain breed of dog and, rarely, in human

sweat. A bintaurong in a clean zoo, at night, spread a very sweet odour which seemed to me to be exactly like that of the freshest, best-quality fragrant rice. It is to be noted, however, that civetone, which has a different chemical structure smells like 2AP as asserted by many people.

The fresh flowers of *Bassia latifolia* emit a smell which resembles the fragrance of rice and has also been described as mousey by a European. Paper-chromatography of this flower extract and synthetic 2AP suggest that the flower aroma is 2AP (ref. 10). Further work with GLC and HPLC may establish the contention and in that case this may be the first example of 2AP traced in the scent of flower.

Biosynthesis

The biosynthesis of 2AP is not clear. It may be enzymatic or, simply, a Maillard reaction, a principle described about 80 years ago but which is now evoking renewed interest¹¹. A Maillard reaction involving an amino-acid and a sugar may yield numerous products at very many different temperatures. In our attempts the lowest temperature that yields 2AP is 105°C, but in the rice plant this process occurs in the temperature gained from autumn sunshine (~30°C) and in *Bassia* flower, at dawn or evening or night in the spring season and therefore, at a much lower temperature. In some export-quality basmati rice, the sweet 2AP smell is not present in the unboiled grain. Boiling rice leads to further Maillard reaction and production of 2AP.

Unstable molecule

2AP decays very quickly, a fact that may explain why most urban people have no concept of the excessively sweet smell of freshly husked rice grains of many indigenous fragrant varieties. This smell disappears very quickly but even relatively old rice, on boiling, produces 2AP once again, presumably due to Maillard reaction. Buttery *et al.*¹ succeeded in keeping the synthetic molecule (as a hydrochloride) intact for 3 months. We note that the picrate is stable even up to 2 years. In a recent experiment, we found good stability as a citrate salt after 6 months and we hope to test again after one year of preservation.

Utility of 2AP for the plant

We enjoy the aroma of 2AP and probably the tiger uses it as a component of its pheromonal, communicatory signal but what good does this perfume do to the rice plant itself? This, at present, is anybody's guess but recently jasmonic acid and methyl jasmonate, the fragrant molecules of jasmine have been found to be useful as arsenals of the plant for fighting bacterial, viral and fungal attack¹². A fragrant rice variety in West Bengal has recently been noticed to be unusually fungus-resistant¹³. The role of 2AP, if any, in protecting the rice plant may be studied in future.

Somatic embryogenesis and plant regeneration in *Aegle marmelos* – a multipurpose social tree

Aegle marmelos Corr. (Rutaceae) locally called 'Beal' is an economically important multipurpose social tree of the Indian subcontinent. Micropropagation of necessary useful trees enables rapid propagation and hastens the availability of new cultivars¹. Regeneration from hypocotyl², cotyledon³, leaf⁴, nucellus^{5,6} and zygotic embryos⁷ was achieved. However, plant regeneration via somatic embryogenesis has not yet been reported in *A. marmelos*. Somatic embryogenesis has been achieved in a number of angiosperms but success has been limited with woody species^{8–11}. Here we report somatic embryogenesis of *A. marmelos* by using zygotic embryos.

Seeds from mature, green unripe fruits of 20-year-old *A. marmelos* were surface disinfected with 0.1% mercuric chloride. Embryo axis containing one-fourth part of cotyledons was excised from decoated seeds and cultured on solid Murashige and Skoog (MS) medium¹² containing 20% coconut water, 4% sucrose, 2,4-dichlorophenoxyacetic acid (2,4-D) and benzyladenine (BA) at different concentrations (0.5–2.0 μM) and combinations. After six weeks the somatic embryos were transferred into test tubes containing half strength MS medium supplemented with 2% sucrose and 1.0 μM BA. The cultures were incubated at $26 \pm 1^\circ\text{C}$ with 16 h photope-

riod (50–70 $\mu\text{mol m}^{-2} \text{s}^{-1}$, Phillips white fluorescent lamps).

White globular somatic embryos appeared as loose structures after 30 days on explants (Figure 1a). The highest response in number of explants producing somatic embryos (18%) and the number of somatic embryos per explant (12) was observed in presence of 2,4-D (1 μM) and BA (1 μM) as per observations recorded after 42 days. Media supplemented with 2,4-D alone did not produce any somatic embryos. In combination with BA (0.5–2.0 μM), 2,4-D at greater than 1.00 μM also showed inhibitory effects on the induction of somatic embryos.

After six weeks of culture initiation, somatic embryos were transferred to half-strength MS medium with 2% sucrose and 1.0 μM BA, radicals and apices of the somatic embryos became active within 15 days, cotyledons turned dark green and shoots elongated. This was consistent with observations that somatic embryos of woody species benefit from a reduction in nutrients in the culture medium for germination^{13,14}. More often, calli rather than root, developed at the radicle ends of the somatic embryos (Figure 1b). The conversion percentage was approximately 12% (Figure 1c). Culture conditions such as growth-regulator concentration and incubation time may affect germination and conversion into plants.

This is the first report on somatic embryogenesis in *A. marmelos*. Similar reports on *Liriodendron*¹⁵, *mango*¹⁶ and *lyohee*¹⁷ have appeared earlier. However, somatic embryogenesis in the present studies could prove useful in improving a multipurpose tree, *A. marmelos*.

Figure 1 a–c. Somatic embryogenesis in *A. marmelos*. a, Formation of globular somatic embryos on zygotic embryo in MS + 1.0 μM 2,4-D + 1.0 μM BA after 5 weeks of culture. b, Somatic embryo developed into shoot on 1/2 MS + 1.0 μM BA after 5 weeks of culture; note formation of callus on radicle portion. c, A complete plantlet developed in the same medium.

PHYSICS AND CHEMISTRY OF SOILS

T. C. Baruah and D. K. Patgiri

This book embodies the inherent concepts, outlines the basic principles, and provides avenues for characterization and rapid quantification of soil physical phenomena and physicochemical processes and their space dependence. There are 13 chapters of great academic as well as practical value.

Each chapter is presented in a systemic manner to facilitate comprehension, detailing the theoretical analysis and outlining the experimental procedures with illustrations, pertinent figures and data analysis, wherever possible. Some of the aspects of study are presented with flow diagrams which facilitate a comprehensive appraisal.

The post-graduate students of agricultural universities/institutes, in particular, and the professionals, working in the fields of Soil Physics, Water Management as well as Soil Chemistry will definitely benefit from this book.

81-224-0981-4 1996 HB 210pp Rs 375

PRINCIPLES AND PRACTICES OF MODERN COAL MINING

R. D. Singh

This book appraises the reader of the present practices of coal mining and also projects the technologies of the future. In writing this book, the author has extensively drawn on the current publications, both Indian and foreign, beside on his own experiences in India and abroad. Case histories from India and abroad have been cited to illustrate the modern technologies of coal mining in various situations. References have been given at the end of each chapter which will enable the readers to acquire further information in the areas of their interest.

This book has been written keeping in view primarily the needs of the students of mining engineering, but it will be of equal interest to the practising mining engineers, mine planners and researchers.

Norbert Wiener and the development of mathematical engineering

Thomas Kailath

1. Introduction

'There is nothing better than concrete cases for the morale of a mathematician. Some of these cases are to be found in mathematical physics and the closely related mathematical engineering...'

So wrote Norbert Wiener in 1949, in an obituary of G. H. Hardy, who reputedly would have shuddered at the thought. [Ironically, Hardy's own major field of number theory has been of great importance for many applications, for example in secure data communications.] This paper will attempt to describe how one particular concrete problem in Wiener's own work – solving the Wiener–Hopf equations encountered in astrophysics – led him, and then a vast host of followers, to chart out several new areas of investigation, and to develop a very significant body of knowledge, which can well go by the name Mathematical Engineering. In the era of the PC, the Internet and the World Wide Web, few of us can be unaware that mathematical engineering has come to play a major role in the world around us. And with this has come, as this paper will describe, an increasing recognition of the seminal role of Norbert Wiener's ideas and influence in the development of this field.

It must be said that the term 'Mathematical Engineering' does not enjoy the currency that the name 'Mathematical Physics' does. Being a younger field, its proponents still focus on more specialized descriptions such as Information Theory, Communications, Control, Signal Processing, Computational Complexity, Image Processing, etc. The names 'System Theory' or even 'Mathematical System Theory' have been advanced but are not universally accepted. However this author believes that the increasing intermingling of the fields mentioned above, with many tools and techniques being successfully applied across them, as well as the tremen-

dous opportunities ahead of them in the Information Era, could well lead to the adoption of Wiener's suggestion. And be that as it may, Wiener's early vision and pioneering contributions will, as mentioned earlier, loom even larger with time. Already in 1962, in a special issue commemorating the 50th anniversary of the effective existence of the IEEE (Institute of Electrical and Electronics Engineers), Lotfi Zadeh, winner of the 1995 IEEE Medal of Honour wrote *'If one were asked to name a single individual who above anyone else is responsible for the conception of system theory, the answer would undoubtedly be 'Norbert Wiener', even though Wiener has not concerned himself with system theory as such, nor has he been using the term "system theory" in the sense employed in this paper'*.

There are many of Wiener's results that have come to be important in mathematical engineering. Although Wiener was apparently never quite secure about his place in the pantheon of scientific innovators, he seemed not to have such doubts about the significance of the particular concrete problem that we shall concentrate on in this paper. This is the Wiener–Hopf equation, which Wiener first encountered in 1931 in astrophysics and then a decade later in the problem of anti-aircraft fire control. I hope to indicate how Wiener's work on this equation has led to the development of a remarkably broad, and deep, range of studies.

In the next section, we shall describe Wiener's beautiful technique of spectral factorization for solving it. In § 3 and 4, we shall note that Wiener encountered the equation again in solving a problem in anti-aircraft fire control and how his 1942 report on this project introduced two fundamental ideas that radically changed the way engineers approached important classes of problems. First is that the communication of information must be formulated as a statistical problem; the second, the introduction of optimization criteria to obtain the limits of performance and replace the earlier 'trial and error' approach to design. From these two ideas has grown the huge flood of activity noted earlier. However to narrow the scope we shall return in the remainder of the paper to a specific problem studied by Wiener – filtering signals out of noisy observations. After describing his results, we shall turn to some of the mathematical developments following from it. First we shall show in

The work was supported by the Advanced Research Projects Agency of the Department of Defense and was monitored by the Air Force Office of Scientific Research under Grant No. F49620-93-1-0085.

First published in the *Proceedings of Symposia in Pure Mathematics*, 1996, 60 (tentative), published by the American Mathematical Society.

Thomas Kailath is Hitachi America Professor of Engineering at Stanford University, Stanford, CA 94305-4055, USA.

§ 6, how, while Wiener was not quite successful in extending his results to the case of multiple time series, this can be done by the introduction of state-space and Markov process descriptions. Somehow Wiener himself never really focused on the Markov property. As we shall see, the state-space description introduces the concept of recursive solution algorithms and enables straight-forward extension to nonstationary/time-variant versions of the filtering problem. In § 7, we shall examine a widely used finite-time prediction problem, which has been generalized by using the concept of displacement structure. Finally in § 8, we shall introduce the nonlinear filtering problem, which is still open, but for which a key tool is martingale theory, the prototype for which was the Wiener (Brownian motion) stochastic process.

2. The Wiener-Hopf equation

Given $\phi_{11}(\cdot)$ and $\phi_{12}(\cdot) \in \mathcal{L}_1(\infty, -\infty)$, $\phi_{11}(\cdot)$ even and positive definite, find $k(\cdot)$ such that

$$\phi_{12}(t) = \int_0^\infty \phi_{11}(t-\tau)k(\tau)d\tau, \quad t \geq 0 \quad (1)$$

where $k(t) = 0$, $t < 0$. Equations of this type were apparently first introduced by Hvol'son (1894, Leningrad) while studying the scattering of light by milk glass, and later (ca 1920), by E. A. Milne, K. Schwarzschild and others in problems in astrophysics.

While such equations attracted considerable attention, explicit analytical solution was long thought to be impossible, a point of view that, in the words of M. G. Krein (1958) 'was refuted in 1931 by the brilliant achievement of E. Hopf and N. Wiener'. In fact, so striking in its ingenuity and simplicity was their solution that not only the technique, but the equation itself came to be known by the name 'Wiener-Hopf'. Moreover a decade later, Wiener encountered the equation again, with even more significant consequences!

The genesis of these events was apparently (Pincus (1981)) a summer evening with E. Hopf at Wiener's country home in New Hampshire, where characteristically Wiener asked his visitor about challenging open problems in his field. The next morning Wiener came down for breakfast with a 'solution'. It in fact needed some reworking, which was done and the result was published in 1931, with the unusual (for mathematicians) nonalphabetical ordering of names. We shall briefly outline the Wiener-Hopf idea (ignoring various technical assumptions, for which see, e.g., Krein (1958)).

The tools used in the solution had in fact largely been developed by Wiener himself in collaboration with R. E. A. C. Paley. First were the properties in the complex plane of Fourier transforms of one-sided (or 'causal')

functions. One motivation for Wiener's interest in such topics may have been his study of electrical networks and his 1931 patent (with Y. W. Lee, Sc. D., Elec. Engg.) on a new cascade realization (based on Laguerre functions), of network impedance functions, known to mathematicians as Caratheodory (or positive-real) functions. In any case, for us the key property is that (again under certain conditions) a function $k(\cdot)$ such that $k(t) = 0$, $t < 0$, has a Fourier transform $\mathcal{K}(\omega)$ whose extension to the complex plane, $\mathcal{K}(s)$, $s = \sigma + i\omega$, is analytic in the RHP, $\sigma > 0$.

The second tool was the closely related fact that such extensions of nonnegative even functions

$$0 \leq \Phi(\omega) = \Phi(-\omega) \quad -\infty < \omega < \infty$$

have unique canonical factorizations

$$\Phi(s) = \Psi(s)\Psi^*(-s^*), \quad s = \sigma + i\omega \quad (2)$$

where $\Psi(s)$ is analytic and bounded in the RHP, $\sigma > 0$, while $\Psi^{-1}(s)$ is analytic in the RHP, $\sigma > 0$. It may be noted that Wiener had recognized such functions, $\Phi(\cdot)$, as Fourier transforms of autocorrelation (real, even and positive definite) functions and described their significance as power spectral density functions. An equivalent result was discovered by Khinchin in 1934, leading to the so-called famous Wiener-Khinchin theorem. [It turns out that they had been anticipated by no less than Albert Einstein, in a two-page 1914 sketch answering a question raised by a friend on measuring the 'power' of meteorological time-series!] Now for the Wiener-Hopf technique.

We first extend the equation (1) to the whole line by introducing the function

$$g(t) = \phi_{12}(t) - \int_0^\infty k(\tau)\phi_{11}(t-\tau)d\tau \quad -\infty < t < \infty.$$

By the fact that (1) only holds for $t \geq 0$, we know that $g(\cdot)$ is one-sided, but 'anticausal',

$$g(t) = 0 \quad t \geq 0$$

unlike the unknown 'causal' function $k(\cdot)$,

$$k(t) = 0 \quad t < 0.$$

Of course now we have two unknown functions, $g(\cdot)$ and $k(\cdot)$, but give us a moment. Take Fourier transforms in the complex plane to get

$$G(s) = \Phi_{12}(s) - \mathcal{K}(s)\Phi_{11}(s).$$

Now use the canonical factorization (2) to write

$$\frac{G(s)}{\Psi^*(-s^*)} = \frac{\Phi_{12}(s)}{\Psi^*(-s^*)} - \mathcal{K}(s)\Psi(s)$$

But by construction $G(s)$ and $1/\Psi^*(-s^*)$ are analytic in the LHP, $\sigma < 0$, while $\mathcal{K}(s)$ and $\Psi(s)$ are analytic in the RHP, $\sigma > 0$. Equivalently the time function obtained by

inverse Fourier transformation (IFT) of $G(s)/\Psi^*(-s^*)$ will be zero for $t \geq 0$ (anticausal), while the time function corresponding to $\mathcal{K}(s)\Psi(s)$ will be zero for $t < 0$ (causal). This means that the latter time function must be equal to the $t \geq 0$ portion of the IFT of $\Phi_{12}(s)/\Psi^*(-s^*)$, leading to the famous formula for the solution of the Wiener-Hopf equation (1)

$$\mathcal{K}(s) = \frac{1}{\Psi(s)} \int_0^\infty dt e^{-st} \oint \frac{\Phi_{12}(p)}{\Psi^*(-p^*)} e^{pt} \frac{dp}{2\pi i}. \quad (3)$$

We shall return to this equation in § 5, after an apparent digression.

3. The problem of anti-aircraft fire control

Seeking eagerly to contribute to the War effort, Wiener submitted a proposal to the National Defense Research Council (NDRC) for a novel parallel computing machine for solving partial differential equations, as arising for example in aerofoil design problems. However, the proposal was deemed unlikely to be completed in a reasonable time frame. Wiener cast about for a more relevant problem and hit upon the problem of anti-aircraft fire control. In Dec. 1940, he sought and won a (\$2350!) project on '*design of a lead or prediction apparatus in which, when one member follows the track of an airplane, another anticipates where the airplane is to be after a fixed lapse of time*'. Under certain assumptions, the problem can be reduced to one of finding an effective method of approximating an exponential function by a rational function of suitable order, which Wiener proposed to do by using ideas from his earlier (ca 1930) work with Y. W. Lee on network synthesis. However working with the engineer hired for the project, Julian Bigelow, Wiener came to see in a few months, that because of noise and of model uncertainties, a satisfactory engineering solution demanded explicit consideration of the *statistical nature* of the problem, and also the use of an *optimization criterion*. Effectively assuming that the airplane trajectories were sample functions of a stationary and ergodic random process, and imposing the requirements of a *linear apparatus* and of the *mean-square-error criterion* led him again to the Wiener-Hopf integral equation. So the solution was at hand! But unlike the apocryphal mathematician, who promptly drops a problem when he reduces it to one that has already been solved, Wiener realized that much more was needed for a real engineering solution.

In fact, Wiener's project reports make a beautiful (and perhaps the first) case study in how to use the theory of *optimal* solutions in the real world. First, he confined himself to the practically most significant case: rational power spectral densities, necessary for '*the actual realization in the field by a finite electrical or mechanical structure*'. Here are a few other quotations: '*the detailed*

design of a filter involves ... choices ... which must be justified economically'. '*Let us see ... the stages that are needed. The first stage determines the irreducible error, i.e., the error which cannot be reduced by any delay whatever. ... Next, ... , we can determine a reasonable delay, such that the delay error is not large in comparison with the irreducible error, the sense of 'large' depending on the problem.*' Writing about the assumption of stationarity, he reassures the user that while the available '*statistical information will in fact never be complete, as our information does not run indefinitely for back into the past, it is a legitimate simplification of the facts to assume that the available information runs back much farther into the past than we are called upon to predict the future*'. And so on. Few mathematicians before Wiener had such an interest in the many issues arising in actual implementation.

Despite all this, however, the results actually obtained in field trials were not satisfactory, and the project was terminated. But Wiener wrote up the theoretical results obtained in the course of the work, along with some mathematical preliminaries and his philosophical views on the nature of his new approach to the field of communication engineering, in a remarkable 1942 monograph '*Extrapolation, Interpolation and Smoothing of Stationary Time Series*'. It was later declassified and published in 1949 by J. Wiley and the MIT Press. The classified report was widely circulated, while the engineers of the day were hard pressed to follow its contents, it was closely studied by mathematicians such as N. Levinson and R. Philips at MIT, and H. W. Bode, C. E. Shannon, R. Blackman and others at Bell Laboratories. They all wrote up expositions and variations of Wiener's results, some of which we shall mention later.

While preparing his report, Wiener was made aware (by W. Feller) that some-what earlier, and apparently as a purely mathematical investigation, the famous Soviet mathematician A. N. Kolmogorov had studied the prediction problem for general discrete-time stationary processes. The approaches were quite different: Wiener's concrete and focused on applications, Kolmogorov's more abstract and more general. Though later both the methodologies – concrete and abstract – became useful in applications, it was Wiener's work that had a greater impact on electrical engineering, far beyond the original problem and solution.

4. Two new paradigms

In fact, Wiener was quite aware (and perhaps too much so) of the revolutionary significance of his work and ideas, and he stated his views quite emphatically in his 1942 monograph and in various other talks and papers: several passages from these works are quoted here, to show the clarity and prescience of Wiener's thinking.

We begin with his clear and forceful statement of the **statistical nature of the communication problem**. Thus on p. 2 of his monograph:

'Communication engineering concerns itself with the transmission of messages. For the existence of a message, it is indeed essential that variable information be transmitted. The transmission of a single fixed item of information is of no communicative value. We must have a repertory of possible messages, and over this repertory a measure determining the probability of these messages.'

'A message need not be the result of a conscious human effort for the transmission of ideas. For example the records of current and voltage kept on the instruments of an automatic substation are as truly messages as a telephone conversation.'

And then on p. 4:

'A statistical method, as for example a method of extrapolating a time series into the future is judged by the probability with which it will yield an answer correct within certain bounds, or by the mean (taken with respect to probability) of some point, i.e., function or norm of the error contained in its answer.'

'No apparatus for conveying information is useful unless it is designed to operate, not on a particular message, but on a set of messages, and its effectiveness is to be judged on the way performs on the average on messages of this set. ... The apparatus to be used for a particular purpose is that which gives the best result 'on the average' in an appropriate sense of the word 'average'.'

To those now familiar with Information Theory, presented by Shannon in 1948, and Signal Detection Theory as presented by P. M. Woodward and others in the early 1950s, it is worth emphasizing that the above passages were written in 1942. As one major illustration of their influence, we may note Shannon's gracious acknowledgement at the end of his magnificent 1948 paper founding Information Theory:

'Credit must also be given to Professor Norbert Wiener, whose elegant solution of the problems of prediction and filtering has considerably influenced the writer's thinking in this field.'

But there is more. Going beyond the statistical problems he had studied, Wiener stressed the possibility of formulating a variety of engineering problems as *optimization* problems, so that *performance limits* may be calculated and *reasonable* solutions sought; this stands in sharp contrast to many earlier *trial and error* methods:

'These specifications give us an optimum filter to fit the situation exactly, whereas the earlier methods designed filters to certain specifications concerning

passbands, sharpness of cut-off, etc., which stood in no obvious relation to the actual demands of a problem and had to be adjusted to these by the process of trial and error [N. Y. Acad. Sci. lecture, Oct. 1946].'

and again from his 1942 monograph:

'Prediction and filtering do not exhaust the capacity of our methods. They may be applied whenever an ideally desirable linear operation ... is in fact not strictly realizable, although an approximation may be realized.'

In particular, Wiener suggested that his ideas could be applied to the design of compensators for control systems. This suggestion was picked up in the Ph D research of R. Newton at MIT, who, along with L. Gould and J. Kaiser, wrote a book on the topic entitled *Analytical Design of Linear Feedback Controls*, Wiley, 1957. From it, we may quote passages that clearly echo Wiener's early insights (in the fifties, authors were not as gender conscious as they are now):

'... The analytical design procedure has several advantages over the trial and error method, the most important of which is the facility to detect immediately and surely an inconsistent set of specifications. The designer obtains a 'yes' or 'no' answer to the question of whether it is possible to fulfill any given set of specifications; he is not left with the haunting thought that if he had tried this or that form of compensation he might have been able to meet the specifications.'

'... Even if the reader never employs the analytical procedure directly, the insight that it gives him into linear system design materially assists him in employing the trial and error design procedure.'

However more than 50 years later, Wiener's message is apparently still worthy of repetition. Thus, let us quote from a very recent text book by M. Green and D. Limebeer, *Linear Robust Control*, Prentice-Hall, 1995:

'One does not want to waste time trying to solve a problem that has no solution, nor does one want to accept specification compromises without knowing that these are necessary. A further benefit of optimization is that it provides an absolute scale of merit against which any design can be measured – if a design is already all but perfect, there is little point in trying to improve it further.'

'The aim of this book is to develop a theoretical framework within which one may address complex design problems with demanding specifications in a systematic way.'

We continue with some further remarks from this book on the Wiener ideas, though the authors here cite

also the work of R. E. Kalman, which we shall discuss in a later section. From p. 2, we quote (note the 'free ride' that Hopf gets; he perhaps was completely unaware of these applications):

Wiener-Hopf-Kalman optimal control

'The first successes with control system optimization came in the 1950s with the introduction of the Wiener-Hopf-Kalman (WHK) theory of optimal control. At roughly the same time the United States and the Soviet Union were funding a massive research program into the guidance and maneuvering of space vehicles. As it turned out, the then new optimal control theory was well suited to many of the control problems that arose from the space program.'

'... [A] revolutionary feature of the WHK theory is that it offers a true synthesis procedure. Once the designer has settled on a quadratic performance index to be minimized, the WHK procedure supplies the (unique) optimal controller without any further intervention from the designer.'

However, the major motivation for Green and Limebeer's 1995 book was the fact that they were introducing a new (so-called H_∞) formulation:

'In contrast to experience with aerospace applications, it soon became apparent that there was a serious mismatch between the underlying assumptions of the WHK theory and industrial control problems. Accurate models are not routinely available and most industrial plant engineers have no idea as to the statistical nature of the external disturbances impinging on their plant'

Worst-case control: H_∞ optimization

' H_∞ optimal control is a frequency-domain optimization and synthesis theory that was developed in response to the need for a synthesis procedure that explicitly addresses questions of modeling errors.'

Ironically, the new H_∞ theory can be regarded as Wiener-Kalman theory, but in Krein space rather than in Hilbert space. More on this later.

Here, however, as a final quotation from Wiener's own monograph, let us present one that illustrates Wiener's keen insight into what mathematical refinements are relevant to engineers. Engineering textbooks are often still concerned about the level of rigor at which to present Fourier Theory – should one worry about pointwise convergence, L_2 convergence, etc? Wiener cuts right to the heart of the matter:

'Up to the present we have been treating the Fourier series as a purely formal expression without any regard to whether it converges or not. ... Now it is obvious that no physical quantity can be observed for a single precise value of t Thus all functions of t are

for the physicist averages over small ranges of t rather values of a precise point of t .' [He goes on to very simply show that] *'all local averages of the formal [Fourier] series [of $f(t)$] converge to the local average of $f(t)$. As we have pointed out, this is all that we need to make a practical employment of the Fourier series for $f(t)$.'*

This is the approach that later in 1948 L. Schwartz elaborated in his theory of distributions which, among many other things, made rigorous the widespread use of impulsive functions by engineers. I cannot resist remarking that Wiener also uses the 'Sampling Theorem for Bandlimited Functions', first derived by J. M. Whittaker in 1915, but to this day widely cited as Shannon's Sampling Theorem. There are several other little gems in Wiener's report, now fortunately also available in an MIT Press paperback entitled 'Time Series'. But let us now return to some more explicit mathematical problems.

5. The Wiener filter

The appearance in 1949 of Wiener's monograph, and of Shannon's work on Information Theory, generated a huge wave of activity in, to use Wiener's phrase, 'mathematical engineering'. A striking range of mathematics has and is being used in these studies, as can be seen by glancing through, for example, the IEEE Transactions on Information Theory, on Automatic Control, on Signal Processing, on Circuits and Systems, on Image Processing, etc. Many of the algorithms were too complex for implementation till about five to ten years ago, but the pace of technology insertion is accelerating.

In the rest of this paper, we shall discuss one of the directions most closely related to Wiener's own work, focusing on some problems left open by him: spectral factorization of matrix-valued rational spectral densities; finite-time problems/nonstationary processes; nonlinear estimation/random signal detection. The idea is to give a glimpse of part of the wide range of consequences arising from just one of Wiener's mathematical contributions.

We begin with a review of the so-called (causal and noncausal) Wiener filters. A filter is a selective device, e.g., one that allows the transmission of certain frequency regions (the passband) and rejects certain other regions (the stop band). In filtering signals out of a combination of the signals and additive noise, the conventional solution was a device that rejects as much of the noise as possible while passing the signal through undistorted. If as is usually the case, the signal is band-limited (i.e., occupies a limited frequency range) while the noise is wideband, the solution is the so-called Ideal Filter, with unit gain in the frequency regions of the signal and zero gain elsewhere. Wiener pointed out that if

the signal is a random process, one might better be more concerned about regions where the power spectrum of the signal is much larger than that of the noise, with proper weighting to be assigned to different frequency regions depending upon the choice of an optimization criterion. The most fruitful has been Wiener's own choice of a least-squares criterion.

To be specific, consider the problem of estimation the value at a given time t of a stochastic signal process $s(\cdot)$ given the noisy observations

$$y(\tau) = s(\tau) + v(\tau) \quad -\infty < \tau < \infty \quad (4)$$

by using a linear time-invariant filter $h(\cdot)$ such that

$$\hat{s}(t) = \int_{-\infty}^{\infty} h(t-\tau)y(\tau)d\tau$$

satisfies (E denotes expectation)

$$E|s(t) - \hat{s}(t)|^2 = \text{minimum.}$$

Under the assumption that the processes $\{s(\cdot), v(\cdot)\}$ are zero mean and jointly stationary, it is not hard to check that the optimum filter must satisfy the equation

$$\phi_{sy}(t) = \int_{-\infty}^{\infty} h(t-\tau)\phi_{yy}(\tau)d\tau$$

where the $\phi(\cdot)$ are the autocorrelation functions

$$\phi_{sy}(t) = Es(\sigma+t)y^*(\sigma), \quad \phi_{yy}(t) = Ey(\sigma+t)y^*(\sigma).$$

This equation is easily solved by Fourier transformation to yield (using capitals for the transforms)

$$H(\omega) = \frac{\Phi_{sy}(\omega)}{\Phi_{yy}(\omega)}.$$

When the signal and noise processes are uncorrelated with each other, this reduces to

$$H(\omega) = \frac{\Phi_{ss}(\omega)}{\Phi_{ss}(\omega) + \Phi_{vv}(\omega)}. \quad (5)$$

To reflect the fact that the noise has a much higher frequency range than the signal, engineers often assume that the noise is *white*,

$$\Phi_{vv}(\omega) = R > 0, \quad -\infty < \omega < \infty. \quad (6)$$

Such noise processes of course fall out of the scope of the usual theory of stationary processes, since for one thing, the IFT of $\Phi_{vv}(\omega)$ is a delta function. And, in fact, since to have finite power all physical processes must have spectra that decay to zero as $\omega \rightarrow \infty$, white noise is nonphysical as well. Yet it is widely used, as a model, for several important (mathematical and physical) reasons that we do not have time to explain here. However, it is interesting to see Wiener's free use of the white noise model, which is important for many reasons, both theoretical and practical:

'As for (the noise), we shall take a case which, although not formally contained in the theory we have

given, constitutes the limiting case of it, and one of the greatest importance in practice. This is the case in which the noise input is due to a shot effect and has an equipartition of power in frequency. Theoretically, of course, this is not strictly realizable, as it would demand an infinite power; practically as in the case of Plank's law in optics, it may hold within the limits of observation up to frequencies of a magnitude so great that they are no longer of interest for our particular problem.'

To return to our problem, with the white noise assumption, we can see that

$$H(\omega) = \frac{\Phi_{ss}(\omega)}{\Phi_{ss}(\omega) + R} \rightarrow \frac{\Phi_{ss}(\omega)}{R} \text{ as } R \rightarrow \infty.$$

On the other hand, as $R \rightarrow 0$, $H(\omega)$ tends to the ideal filter (with unit gain in the passband of the signal), but this is not the optimum filter when $R \neq 0$. As $R \rightarrow \infty$, we note that $H(\omega) \rightarrow \Phi_{ss}(\omega)/R$, so that the filter tends to reinforce frequencies where $\Phi_{ss}(\omega)/R > 1$, and to suppress the signal in regions where $\Phi_{ss}(\omega)/R < 1$. This fits, in hindsight, with our intuition, but the theory is necessary to tell us what to do for arbitrary values of R , or for nonwhite (often called coloured) noise.

The above solution, though given by Wiener, does not use the Wiener-Hopf equation, because we are assuming that the process $y(\cdot)$ is observed over all time instants, past as well as future. When the observations of $y(\cdot)$ are restricted to the past, we have to solve a Wiener-Hopf equation, which when (4) and (6) hold, takes the form

$$Rk(t) + \int_0^{\infty} k(\tau)\phi_{ss}(t-\tau)d\tau = \phi_{ss}(t), \quad t \geq 0. \quad (7)$$

With the white noise assumption, the formula for the solution takes the striking form (apparently first noted by Yovits and Jackson (1960))

$$K(\omega) = 1 - R^{1/2}\Psi^{-1}(\omega). \quad (8)$$

In other words, the *canonical spectral factorization* completely defines the estimator in the additive white noise case!

One might justly wonder about the physical significance of the canonical factorization, and the stochastic problem allows a nice (and far reaching) interpretation, first given by Bode and Shannon (1950), and independently (and in somewhat more general form) in a lesser-known paper of Zadeh and Ragazzini, also appearing in 1950. These authors noted that passing the observations process $y(\cdot)$ through a linear filter with transfer function $\Psi^{-1}(\omega)$ gives us a process $e(\cdot)$ with power spectrum (using well-known formulas),

$$\Phi_{ee} = \Psi^{-1}(\omega)\Phi_{yy}(\omega)\Psi^{-*}(-\omega) = I.$$

Therefore, we can interpret the first term $\Psi^{-1}(\omega)$ in the general Wiener-Hopf formula (3)

$$k(\omega) = \frac{1}{\Psi(\omega)} \left[\int_0^\infty dt e^{-j\omega t} \oint \frac{\Phi_{12}(p)}{\Psi^*(-p^*)} e^{pt} \frac{dp}{2\pi i} \right],$$

as allowing us to replace the observations process $y(\cdot)$ by a much simpler stochastic process $e(\cdot)$, for which the problem of estimating a related stochastic process $s(\cdot)$ turns out to be much simpler: when $\phi_{11}(\cdot)$ in the Wiener-Hopf equation

$$\phi_{12}(t) = \int_0^\infty \phi_{11}(t-\tau) k(\tau) d\tau, \quad t \geq 0$$

is a delta function, the solution is immediate: $k(t) = \phi_{12}(t)$, $t \geq 0$.

One might wonder if there is a 'loss of information' in going from the original observed process $y(\cdot)$ to the white process $e(\cdot)$? The answer is no, because by the fact that the canonical factor $\Psi(s)$ and its inverse $\Psi^{-1}(s)$ have the property that they are analytic in the RHP, one can pass (recall the Paley-Wiener results quoted in § 3) from $y(\cdot)$ to $e(\cdot)$ and from $e(\cdot)$ back to $y(\cdot)$ by causal and stable linear operations. Since

$$\mathcal{F}^{-1}\{\Phi_{ee}(\omega)\} = Ee(\tau+t)e^*(\tau) = \delta(\tau) = 0, \quad \tau \neq 0$$

the value of $e(\cdot)$ at any instant is uncorrelated with its values at any other instant, and therefore every observation, $e(t)$, brings *new* information, which cannot be said about a (corrected) nonwhite process. The process $e(\cdot)$ is called the *innovations process* of $y(\cdot)$; we shall return to it in a more general context in § 8. The innovations concept has been useful in extensions of Wiener filtering theory to nonstationary processes and to nonlinear problems, see e.g., Kailath (1970), Davis (1977) and Fujisaki *et al.* (1971). We may note that, Kolmogorov's more general approach to the discrete-time prediction problem (1939), (1941) was based on the use of the innovations process, which avoids (or rather trivializes, as we noted earlier) the use of the Wiener-Hopf equation. Thus somewhat ironically, Kolmogorov's more abstract approach ultimately became more powerful than Wiener's more concrete approach, a phenomenon, mathematicians may be pleased to know, that is not uncommon in applications.

6. Extensions: Matrix spectral factorization

Wiener's monograph inspired various attempts at extensions – to finite-time nonstationary problems, and to vector-valued processes in particular. When observations are only available over a finite time, say $(0, t)$ rather than $(-\infty, t)$, the W-H equation is replaced by one of 'W-H type',

$$h(t, s) + \int_0^t h(t, \tau) \phi(\tau - s) d\tau = \phi(t - s), \quad 0 \leq s \leq t. \quad (9)$$

No general methods were or are known for its solution, and a vast literature developed on various special cases,

tricks, etc; so much so that a 1958 editorial by P. Elias urged no more work on 'Two Famous Papers'. One generic title was 'The Optimum Linear Mean Square Filter for Separating Sinusoidally Modulated Triangular Signals from Randomly Sampled Stationary Gaussian Noise, with Applications to a Problem in Radar'. (The other: 'Information theory, Photosynthesis and Religion'.)

The apparent mess was cleaned up by the use, by R. E. Kalman in 1960, of the *state-space description* of process with rational spectral densities. Such descriptions are actually of much older vintage, see, e.g. a paper by and were used by Wang and Uhlenbeck (1930) on Markov models for noise processes. Doob wrote two long papers on them in 1944 and 1949 but, alas, did not mention them in his very influential 1953 book! Had he done so many developments might have occurred much earlier.

The so-called Kalman (or sometimes Kalman-Bucy) filter has been widely discussed in a host of a papers and textbooks, e.g., Anderson and Moore (1979), Kailath (1981). It gains its power, as just noted, from the introduction of state-space models, which turns out to be equivalent to modelling stochastic processes as linear combinations of the components of a vector-valued Markov process. Briefly, we model a scalar process $s(\cdot)$ with an n -th order rational spectral density as

$$\begin{cases} s(t) = Hx(t) \\ \dot{x}(t) = Fx(t) + u(t) \end{cases} \quad t \geq t_0 \quad (10)$$

where $H \in \mathcal{C}^{1 \times n}$, $F \in \mathcal{C}^{n \times n}$ are known matrices, $u(\cdot)$ is an $n \times 1$ vector-valued zero-mean white noise process, with

$$\langle u(t), u(s) \rangle \triangleq Eu(t)u(s)^* = Q\delta(t-s),$$

and the initial *state*, $x(t_0)$, is such that

$$\begin{aligned} \langle x(t_0), 1 \rangle &= Ex(t_0) = 0, \quad \langle x(t_0), x(t_0) \rangle = \Pi_0, \\ \langle x(t_0), u(t) \rangle &= 0. \end{aligned}$$

The matrices $Q \in \mathcal{C}^{n \times n}$ and $\Pi_0 \in \mathcal{C}^{n \times n}$ are also assumed to be known.

We use the inner product notation to follow Kolmogorov in assuming that (zero-mean) random variables defining a (second-order) stochastic process live in a Hilbert space (or Hilbert module, when the random variables are vector-valued). Of course we are stretching this formulation when we deal with white noise processes, but rigor can be restarted by regarding a white noise process as the formal derivative of a process with orthogonal increments.

Though the linear system relating the stochastic input process $u(\cdot)$ to the output stochastic process is time-invariant, the process $s(\cdot)$ will in general be nonstationary, because the 'transients' arising from the fact that the input is switched on at time t_0 and does not begin in the remote past. In fact, it is not hard to see that

$$\Pi(t) = \langle x(t), x(t) \rangle$$

will obey

$$\Pi(t) = F\Pi(t) + \Pi(t)F^* + Q, \quad \Pi(t_0) = \Pi_0. \quad (13)$$

However, when F is 'stable', i.e., all its eigenvalues have strictly negative real parts, then it turns out that the process $s(\cdot)$ will be stationary if the initial state variance is chosen as

$$\Pi(t_0) = \Pi,$$

where Π is the unique nonnegative definite solution of the (Lyapunov) equation

$$0 = F\Pi + \Pi F^* + Q. \quad (14)$$

Now since we have introduced matrix notation, we can as well take the step of regarding $s(\cdot)$ as a $p \times 1$ vector-valued process, so that $H \in \mathcal{C}^{p \times n}$. The filtering problem is now a 'multichannel' problem of attempting to find

$\hat{s}(t)$ = the linear least-squares estimate of $s(t)$ given $\{y(\tau), t_0 \leq \tau < t\}$,

where

$$y(t) = s(t) + v(t), \quad t \geq 0 \quad (15)$$

and $v(\cdot)$ is a white noise process such that

$$\left\langle \begin{bmatrix} u(t) \\ v(t) \end{bmatrix}, \begin{bmatrix} u(s) \\ v(s) \end{bmatrix} \right\rangle = \begin{bmatrix} Q & S \\ S^* & R \end{bmatrix} \delta(t-s), \quad (16)$$

where $S \in \mathcal{C}^{n \times p}$ and $R \in \mathcal{C}^{p \times p}$ are also assumed to be known *a priori*. The presence of the additive white noise is essential to get useful results, and so it is assumed that R is strictly positive definite, $R > 0$.

It is widely believed that the reason for the greater scope of the Kalman theory (applying to vector-valued but finite-dimensional) stationary processes also to (finite-dimensional) nonstationary process is in fact that it starts, as above, with a model for the process $s(\cdot)$ rather than with power-spectral or covariance data. However this is not true – the Wiener and Kalman approaches become equivalent if one carries over the state-space characterization of the process to its power-spectra and/or covariance functions.

We shall illustrate this now by using the state-space model to solve a problem not satisfactorily resolved by Wiener and several later researchers – finding an effective way of computing the canonical factorization of a rational power spectral density function matrix. We start by noting that since the transfer function from the input white noise processes $\{u(\cdot), v(\cdot)\}$ to the output process $y(\cdot)$ is

$$[H(i\omega I - F)^{-1} \quad I], \quad (17)$$

the power-spectral density function of $y(\cdot)$ can be computed as

$$\Phi_{yy}(\omega) = [H(i\omega I - F)^{-1} \quad I] \begin{bmatrix} Q & S \\ S^* & R \end{bmatrix} \begin{bmatrix} (-i\omega I - F^*)^{-1} H^* \\ I \end{bmatrix}. \quad (18)$$

An alternative expression can be found by taking the Fourier transform of the covariance function:

$$\phi_y(\tau) = \langle y(t), y(t-\tau) \rangle = \frac{R\delta(t-\tau) + He^{F\tau}N1(\tau) + N^*e^{F^*\tau}H^*1(\tau), \quad (19)$$

where

$$N = \Pi H^* + S \quad (20)$$

and $1(\cdot)$ is the (Heaviside) step function

$$1(t) = \begin{cases} 1 & t > 0 \\ 1/2 & t = 0 \\ 0 & t < 0 \end{cases}$$

The Fourier transform of $\phi_y(\cdot)$ is

$$\Phi_{yy}(\omega) = [H(i\omega I - F)^{-1} \quad I] \begin{bmatrix} 0 & N \\ N^* & R \end{bmatrix} \begin{bmatrix} (-i\omega I - F^*)^{-1} H^* \\ I \end{bmatrix}. \quad (21)$$

Comparing (18) and (21) shows that different 'central' matrices could be used to specify $\Phi_{yy}(\omega)$, some nonnegative definite as in (18), while, the one in (21) is indefinite. It is natural to ask how we can characterize the nonuniqueness of the central matrix? The answer is that we can use *any* central matrix of the form

$$M = \begin{bmatrix} Q + FZ + ZF^* & S + ZH^* \\ S^* + HZ & R \end{bmatrix}, \quad Z = Z^* \quad (22)$$

i.e., where Z is any Hermitian matrix. The choices $Z = 0$ and $Z = \Pi$ give the previous expressions (18) and (21). The fact that any such M yields $\Phi_{yy}(\omega)$ can be verified by a direct (but tedious) calculation. However, a nicer and more useful derivation can be obtained by allowing the random variables to live in an indefinite (Krein space), rather than in Hilbert space.

In a Krein space we can have elements such that $\langle u, u \rangle$ is indefinite or even zero. For example, we could have

$$\left\langle \begin{bmatrix} u^0(t) \\ v^0(t) \end{bmatrix}, \begin{bmatrix} u^0(s) \\ v^0(s) \end{bmatrix} \right\rangle \triangleq \begin{bmatrix} Q^0 & S^0 \\ S^{0*} & R^0 \end{bmatrix} \delta(t-s) = \begin{bmatrix} 0 & N \\ N^* & R \end{bmatrix} \delta(t-s). \quad (23)$$

In view of this, let us add to the original $\{u(\cdot), v(\cdot)\}$, elements $\{u^0(\cdot), v^0(\cdot)\}$ such that (in an obvious notation)

$$\begin{cases} \dot{x}(t) + \dot{x}^0(t) = F(x(t) + x^0(t)) + G(u(t) + u^0(t)) \\ y(t) + y^0(t) = H(x(t) + x^0(t)) + v(t) + v^0(t) \end{cases} \quad (24)$$

where

$$\left\langle \begin{bmatrix} u(t) \\ v(t) \end{bmatrix}, \begin{bmatrix} u^0(t) \\ v^0(t) \end{bmatrix} \right\rangle = 0 \text{ and } \langle y^0(t), y^0(\tau) \rangle = 0. \quad (25)$$

This can be done using earlier formulas (see (5)–(6)) to note that

$$\Phi_{y_0 y_0}(\omega) = [H(i\omega I - F)^{-1} \quad I] \begin{bmatrix} 0 & \Pi^0 H^* + S^0 \\ H \Pi^0 + S^0 & R^0 \end{bmatrix} \begin{bmatrix} (-i\omega I - F^*)^{-1} H^* \\ I \end{bmatrix}, \quad (26)$$

where $\Pi^0 = \Pi^{0*}$ is such that

$$F \Pi^0 + \Pi^0 F^* + Q^0 = 0. \quad (27)$$

From these we conclude that $\Phi_{y_0 y_0}(\omega)$ will be identically zero if we choose

$$S^0 = -\Pi^0 H^*, \quad Q^0 = -F \Pi^0 - \Pi^0 F^* \text{ and } R^0 = 0. \quad (28)$$

Finally setting $Z = -\Pi_0$ gives

$$\begin{aligned} & \left\langle \begin{bmatrix} u(t) + u^0(t) \\ v(t) + v^0(t) \end{bmatrix}, \begin{bmatrix} u(s) + u^0(s) \\ v(s) + v^0(s) \end{bmatrix} \right\rangle \\ &= \begin{bmatrix} Q + Q^0 & S + S^0 \\ S^* + S^0 & R + R^0 \end{bmatrix} \delta(t-s) \\ &= \begin{bmatrix} Q + FZ + ZF^* & S + ZH^* \\ S^* + HZ & R \end{bmatrix} \delta(t-s) \triangleq M \delta(t-s) \end{aligned} \quad (29)$$

exactly as claimed above (see (22)). We see now that the arbitrary matrix Z can be interpreted as the (negative of) the state-variance matrix of a process with zero s -spectrum. However, so far we only have a formal calculation. The significant theorem is the so-called KYP Lemma (see Willems and Trentelman for a recent discussion):

Theorem (KYP Lemma) When $\Phi_y(s) > 0$, $s = j\omega$, then there exists a $Z = Z^*$ such that the central matrix is non-negative definite (i.e., it is the covariance matrix of a collection of genuine random variables).

- We do not need F to be stable; a weaker condition from linear system theory, a subject developed in the engineering literature of the last 30 years, will suffice: the pair $\{F, H\}$ should be detectable, i.e., it should be such that $[H^* s I - F^*]$, $s = \sigma + i\omega$, should be full rank for all $\sigma \geq 0$. Here however we shall, for simplicity, stay with the assumption that F is stable so that we are dealing with a stationary process $y(\cdot)$. There are important corollaries characterizing matrix *positive-real* (Caratheodory) and *bounded-real* (Schur) functions, which are widely encountered in applications. We note also that the Krein space interpretation introduced above can be used to give a simple geometric proof of the lemma; it also leads to several other results, e.g., unifying H_2 and H_∞ control (see, e.g., Hassibi *et al.* (1996)).

However while the KYP Lemma is an important result, which is why we mentioned it here, it is not necessary to use it to obtain a spectral factorization of $\Phi_{yy}(\omega)$. To this end, note that although we cannot make any assertions on the positivity of the central matrix M , defined in (28), the fact that

$$\Phi_{yy}(\omega) = [H(i\omega I - F)^{-1} \quad I] M \begin{bmatrix} (-i\omega I - F^*)^{-1} H^* \\ I \end{bmatrix} > 0 \quad (30)$$

shows that M has at least p positive eigenvalues. [Note that, for each ω , the above expression is the product of a $p \times (n+p)$, an $(n+p) \times (n+p)$ and an $(n+p) \times p$ matrix, which is positive definite (i.e., has p positive eigenvalues). Therefore the central $(n+p) \times (n+p)$ matrix, M , must have at least p positive eigenvalues.]

Now that we have shown that the matrix M has at least p positive eigenvalues for all choices of Z , it is interesting to ask whether Z can be chosen so that M has only p positive eigenvalues and no negative eigenvalues, i.e., if Z can be chosen so that M has minimal rank p . To see that this is indeed possible recall the easily verified factorization (recall that we have assumed the invertibility of R).

$$M = \begin{bmatrix} Q + FZ + ZF^* & S + ZH^* \\ S^* + HZ & R \end{bmatrix} = \begin{bmatrix} I & K \\ 0 & I \end{bmatrix} \begin{bmatrix} \Delta & 0 \\ 0 & R \end{bmatrix} \begin{bmatrix} I & 0 \\ K^* & I \end{bmatrix}, \quad (31)$$

where

$$\Delta(Z) \triangleq Q + FZ + ZF^* - (S + ZH^*)(R(S + ZH^*))^* \quad (32)$$

$$K \triangleq (S + ZH^*)R^{-1}. \quad (33)$$

Therefore $\Phi_{yy}(\omega)$ in (30) can be written as

$$\Phi_{yy}(\omega) = H(i\omega - F)^{-1} \Delta(Z) (-i\omega - F^*)^{-1} H^* + [I + H(i\omega - F)^{-1} K] R [I + H(i\omega - F)^{-1} K]^* \quad (34)$$

The second term on the RHS is $p \times p$ and non-negative definite, so we can immediately obtain a factorization by choosing Z so that it satisfies

$$0 = \Delta(Z) = FZ + ZF^* - (S + ZH^*)R^{-1}(S + ZH^*)^* \quad (35)$$

The only issue is whether the resulting spectral factor has a well-defined inverse, viz., one that when extended into the complex plane is analytic in the right half plan (cf. (2)). There is an interesting result here. The nonlinear algebraic equation (35), which for reasons explained below is called an Algebraic Riccati Equation (or ARE), has many solutions. However it can be shown that when F is stable (or even just when $\{F, H\}$ is detectable), there is one and only one non-negative solution, say P ; moreover, this solution is such that the spectral factor

$$\Psi(s) \triangleq [H(sI - F)^{-1} K + I] R^{1/2}, \quad K = S + PH^* R^{-1} \quad (36)$$

and its inverse

$$\begin{aligned} \Psi^{-1}(s) &\triangleq [H(sI - F)^{-1} K R^{1/2} + R^{1/2}]^{-1} \\ &= R^{-1/2} [I - H(sI - F + KH)^{-1} K], \end{aligned} \quad (37)$$

are both analytic in the right half plane. There are several computationally effective methods of finding the desired nonnegative definite solution of the ARE – a good source is the reprint volume edited by Bittanti *et al.* (1995). So the introduction of the ARE, first done in the Kalman theory, overcame what had been regarded as one of the stumbling blocks to the Wiener theory. A minor quibble is that the factorization is expressed in terms of the parameters $\{F, G, H, Q, R, S\}$ of a particular model for the process rather than in terms of the spectral data. Now for the state-space model, the covariance and the spectral density are fixed by (cf. (19)–(21)) by $\{H, F, N\}$. To use this data, all we need to do is to choose the central matrix M not as in (31), but as (cf. (19)–(22)).

$$\begin{bmatrix} 0 + FZ + ZF^* & N + ZH^* \\ N^* + HZ & R \end{bmatrix} \quad (38)$$

Then proceeding as before, the rank of this matrix can be dropped by choosing Z so that it satisfies

$$0 = FZ + ZF^* - (N + ZH^*)R^{-1}(N + ZH^*)^* \quad (39)$$

which will lead to a factorization of the form

$$\Phi_{yy}(s) = [I + H(sI - F)^{-1}(N + ZH^*)]R^{-1}[\dots]^* \quad (40)$$

The particular choice that will give a factor with an inverse that is analytic in the right-hand plane can be shown to be the unique negative semidefinite, say $-\Sigma$, solution of the ARE (39). The corresponding factor is therefore

$$\Psi(s) = [I + H(sI - F)^{-1}K]R^{1/2}, \quad (41)$$

where we define

$$K \triangleq N - \Sigma H^*, \quad (42)$$

and

$$\Sigma \geq 0, 0 = F\Sigma + \Sigma F^* + (N - \Sigma H^*)R^{-1}(N - \Sigma H^*)^* \quad (43)$$

The reader may have wondered that we used the *same* symbols $\Psi(s)$ and K as in the earlier formula (36) – the reason is that the canonical factorization is unique! [This implies the interesting identity $\Pi = P + \Sigma$, which we shall not explore here.]

To close the story of Wiener filtering, let us note that with the canonical factor in hand, we can really write down the optimal filter by using (8) and (37)

$$\mathcal{K}(s) = I - R^{1/2}\Psi^{-1}(s) = H(sI - F + KH)^{-1}K \quad (44)$$

where K can be found either from the model parameters, as in (36), or from the covariance/spectral parameters, as in (42). This is a reasonably explicit formula for the optimal filter, but another advantage of the state-space formulation is that we can readily write down a state-space model for the filter:

$$\dot{\hat{x}}(t) = (F - KH)\hat{x}(t) + Ky(t), \quad \hat{x}(t_0) = 0 \quad (45)$$

$$\hat{s}(t) = H\hat{x}(t) \quad (46)$$

as can be verified by checking that the transfer function from $y(\cdot)$ to $\hat{s}(\cdot)$ is exactly as in (44). We have used the notation $\hat{x}(\cdot)$ for the state-variable in (45), because in fact we have a bonus: $\hat{x}(\cdot)$ is the linear least-squares estimate of the state $x(\cdot)$ itself (under the assumption that $\{F, H\}$ is observable, i.e., $[sI - F^*H^*]$ has full rank for all $s \in C$).

We close with some remarks that, *inter alia*, will fulfill our promise to explain the name ARE. The first remark is obtained by going back to our state-space model, (10) *seq.* Observe that stationarity arose from a particular choice of initial condition, $\Pi(t_0) = \Pi$ defined as the unique matrix such that

$$\Pi \geq 0, 0 = F\Pi + \Pi F^* + Q$$

For any other choice of $\Pi(t_0)$, or if F is unstable (so that (14) will not have a solution $\Pi \geq 0$), the process $s(\cdot)$ will be nonstationary, with covariance function

$$Es(t + \tau)s^*(t) = He^{F\tau}N(\tau), \quad \tau \geq 0$$

where

$$N(t) = \Pi(t)H^*, \quad \dot{\Pi}(t) = F\Pi(t) + \Pi(t)F^* + Q,$$

It turns out that the previous discussions can all be extended by now working in terms of covariance functions rather than power-spectral-density functions. The key change is that instead of the algebraic (Riccati) equation

$$P \geq 0, 0 = Q + FP + PF^*KRK^*, \quad K \equiv (S + PH^*)R^{-1}$$

we shall have the matrix Riccati differential equation,

$$\dot{P}(t) = Q + FP(t) + P(t)F^* - K(t)RH^*(t), \quad P(t_0) = \Pi(t_0)$$

$$K(t) \triangleq (S + P(t)H^*)R^{-1}$$

When the state is one dimensional, the resulting quadratically nonlinear equation is the one apparently first studied by Jacopo Francesco, Count Riccati, and later introduced by Legendre and others into the calculus of variations. It was introduced into control theory by R. E. Bellman (1957) and the matrix version by especially R. E. Kalman (1960).

Explicit analytic solution of the Riccati equation is impossible in the matrix case. But fortunately, this is a (nonlinear) initial value problem, so it can be solved via a discretization scheme, e.g., in the naive way,

$$P(t + \delta) = P(t) + \delta[Q + FP(t) + P(t)F^* - K(t)RK^*(t) + 0(\delta)], \quad t = 0, 1, 2, \dots$$

Now, an important observation is that once the need for some computer-based iterative algorithm is realized, one might further guess that there is no particular need to restrict oneself to time-invariant systems: one can just as easily consider time-variant models,

$$\dot{x}(t) = F(t)x(t) + v(t), \quad t \geq t_0$$

$$y(t) = H(t)x(t) + v(t)$$

with

$$\left\langle \begin{bmatrix} u(t) \\ v(t) \end{bmatrix}, \begin{bmatrix} u(s) \\ v(s) \end{bmatrix} \right\rangle = \begin{bmatrix} Q(t) & S(t) \\ S^*(t) & R(t) \end{bmatrix} \delta(t-s).$$

Now the (Riccati) iteration is still as before,

$$P(t + \delta) = P(t) + \delta[Q(t) + F(t)P(t) + \dots] + 0(\delta), \quad t = 0, 1, 2, \dots$$

except that we need to store/know the values of the functions $\{F(\cdot), Q(\cdot), \dots\}$.

We have thus arrived at the Kalman-(Bucy) filtering algorithm. There is a vast literature on it, with several significant results and issues. Here, we go on to a different kind of extension of Wiener's results, involving finite-time discrete time series. That discussion will lead us to a concept called *displacement structure*, which actually had its roots in studies of the Riccati equation.

7. Beyond state-space models/displacement structure

In one of several different variations of Wiener's problem, his colleague N. Levinson in 1947 studied a finite-time discrete prediction problem, where the Wiener-Hopf equation was replaced by a set of linear equations with a Toeplitz coefficient matrix. He proposed a fast recursive solution, now known as the *Levinson algorithm*, very widely used in geophysical data processing (beginning in the mid-fifties) and in speech processing (beginning in the mid-sixties). Kolmogorov's (1939) formulation of the prediction problem gives an interesting insight into this algorithm, and led to connections with the work of Szegö (1939) and Geronimus (1939) on orthogonal polynomials, of Schur (1917) on H^∞ functions, and then to new results on Toeplitz-like matrices and more generally matrices with displacement structure (see below).

The Kolmogorov Isomorphism: The identity

$$\langle y_k, y_l \rangle = E_{y_k y_l^*} = r_{k-l} = \oint z^k z^{-l} \frac{dF(z)}{2\pi z} = \langle z^k, z^l \rangle_2$$

allows one to form an isometric mapping between the Hilbert space of random variables spanned by $\{y_k\}$, and the Hilbert space of functions on the unit circle spanned by the $\{z^k\}$.

Then the finite-interval prediction problem: find $\{a_{k,j}\}$ to minimize

$$E \|y_k + a_{k,1}y_{k-1} + \dots + a_{k,m}y_{k-m}\|^2$$

is equivalent to the polynomial approximation problem: find $\{a_{k,j}\}$ to minimize

$$\oint |z^k + a_{k,1}z^{k-1} + \dots + a_{k,m}z^{k-m}|^2 \frac{dF(z)}{2\pi z}.$$

It turns out that around 1920 Szegö had shown that the minimizing polynomials

$$a_m(z) = z^m + a_{m,1}z^{m-1} + \dots + a_{m,m}$$

had the nice property that they were orthogonal to each other w.r.t. the measure $F(z)$. Szegö and others went on to make many studies of these orthogonal polynomials. Among other results, in 1939, Szegö and Geronimus independently discovered that these polynomials obeyed a two-term (rather than the usual 3-term) recursion:

$$a_{m+1}(z) = a_m(z) - k_{m+1}z a_m^{\#}(z), \quad a_m^{\#}(z) = \text{the reciprocal polynomial}$$

where $k_{m+1} = -a_{m+1,m+1}$, the constant term in $a_{m+1}(z)$. This is in fact almost the same as the recursion discovered by Levinson in 1947, except that to obtain a true recursion one needs to be able to compute k_{m+1} in terms of $\{F(z), a_m(z)\}$. This could have been done by Szegö or Geronimus, had they been interested in actual computation; however they were more interested in the asymptotic properties of the polynomials (in fact, a famous Szegö formula is just the formula discovered by Kolmogorov and Wiener for the irreducible error in prediction). A survey of the connections between orthogonal polynomial theory and linear estimation, and their fascinating continuous-time analogs, can be found in Kailath *et al.* (1978).

Later it was discovered that a more farreaching connection could be made with some of the work of I. Schur, who was well ahead of his time with his interest in computation. In 1917, he wrote a remarkable paper giving a computationally efficient solution to the Caratheodory moment problem that, in effect, also gave a fast algorithm for factorizing Toeplitz matrices; Levinson's algorithm factorizes the *inverse* of a Toeplitz matrix. It turns out that Schur's algorithm offers an alternative to the Levinson algorithm: it is somewhat slower for serial computation, but can be much faster for (software or hardware) parallel implementation!

There are many aspects to these algorithms arising from pursuing the prediction problem. One of the most fascinating is the concept of *displacement structure*. One way of motivating it is by asking questions such as the following:

If there are fast algorithms for factorizing Toeplitz matrices, what about factoring non-Toeplitz matrices that are known to have Toeplitz inverses? Similarly, should it be much harder to factor the non-Toeplitz matrix $T_1 T_2$ or $T_1 T_2^{-1} T_3$ than T_1 (or T_2 or T_3) alone?

The answer is that these problems in fact have the same order of complexity as purely Toeplitz problems do. The reason is that what allows fast algorithms for Toeplitz matrices is not their Toeplitzness, which is lost under inversion and under multiplication, but something called *displacement structure*: R has displacement

structure if $R = FRA$, or more generally $\Omega R \Delta = FRA$ has low rank for appropriate (low complexity) matrices $\{\Omega, \Delta, F, A\}$. The interested reader can verify that when $F = A^* = Z$, the lower shift matrix with ones on the first subdiagonal and zeros elsewhere, a Hermitian Toeplitz matrix and its inverse have displacement rank less than or equal to 2. It is not hard to show that products, inverses and Schur complements essentially inherit the displacement structure. This fact can be exploited to obtain a generalized Schur algorithm for the fast recursive factorization of such matrices. Moreover there is a very useful physical structure – a cascade network or generalized transmission line – that can be associated with the generalized Schur algorithm, a fact that has lots of implications and applications. We may mention, among others, problems in linear algebra, inverse scattering, coding theory, complex interpolation, matrix completion, etc. Surveys of these results can be found in Kailath (1987) and Kailath and Sayed (1995).

To end this account, though we should note that the initial stimulus for the development of the concept of displacement structure came not from linear algebra, but from the Wiener-Hopf equation itself, as it was further studied by the astronomer V. A. Ambartsumian (1943) in the former Soviet Union, and S. Chandrasekhar in the USA. It will take too long to make those connections here, and we refer the interested reader to the reviews Kailath (1991), Sayed and Kailath (1995) for some the history and for some of the later developments, including links back to the work of I. Schur.

8. Nonlinear estimation

In the late 1950s, Wiener gave a series of lectures on the problem of nonlinear least-mean squares estimation, which were transcribed into a monograph (Wiener (1958)). Wiener proposed to use a so-called 'Volterra series' characterization of nonlinear systems as a sum of linear + quadratic + ... systems. However this approach had several limitations, especially of computational complexity and the difficulty of approximation (how many or which terms should we keep for a particular nonlinear system?).

The success of the state-space models for the linear problems led to a significant effort to try to obtain similar results for the nonlinear case. Thus suppose we have a nonlinear system, in state-space form,

$$\begin{cases} \dot{x}(t) = f(x(t), t, u(t)), t \geq 0 \\ y(t) = h(x(t), t) + v(t) = s(t) + v(t), \text{ say.} \end{cases}$$

The minimum mean-square estimator of $x(t)$ given $\{y(\tau), \tau < t\}$ is no longer linear, and its computation requires full statistical knowledge of the non-Gaussian processes $x(\cdot)$, $z(\cdot)$ and $y(\cdot)$:

$$\hat{s}(t) = E[s(t) | \mathcal{F}\{y(\tau), \tau < t\}].$$

When $\{x(\cdot), s(\cdot), y(\cdot)\}$ are jointly Gaussian, one has the Kalman filter recursions. But in general, all has an ascending chain of coupled nonlinear equations for which no really satisfactory practical algorithms, or approximations, have been found. Therefore the nonlinear problem is effectively still open.

However there have been several interesting theoretical results. One set arises from the introduction of ideas from martingale theory (with some of the results now being pursued in finance theory and on Wall Street). Martingale theory first enters through the fact that the white Gaussian measurement noise, $v(\cdot)$, of the engineers is the formal derivative of the special process introduced by Wiener in his study of Brownian motion:

$$\int_0^t v(\tau) d\tau = W(t), \text{ the Wiener (-Lévy) process.}$$

The martingale properties of $W(\cdot)$ lead to a striking generalization of the innovations process first introduced in the linear theory. Let us recall from § 5 that with (scalar) observations containing white noise,

$$y(t) = s(t) + v(t), \langle v(t), v(\tau) \rangle = \delta(t - \tau)$$

the optimum linear filter for finding $\hat{s}(\cdot)$ has transfer function (note that now $R \equiv 1$ in (8))

$$K(\omega) = 1 - \Psi^{-1}(\omega).$$

This implies in the time domain that

$$\hat{s}(t) = y(t) - e(t)$$

or that the innovations can be expressed as

$$e(t) = y(t) - \hat{s}(t).$$

Now when we deal with nonlinear operations on white noise, the formal manipulations become harder to justify: linear operations on white noise give smoother processes, but what is the square of white noise? Therefore one now works with integrated processes,

$$Y(t) \triangleq \int_0^t y(\tau) d\tau = \int_0^t s(\tau) d\tau + \int_0^t v(\tau) d\tau = \int_0^t s(\tau) d\tau + W(t)$$

and uses the Ito theory of stochastic integrals, especially as developed by the Japanese and French schools (see e.g., Meyer (1975)).

In this language, one can show (see Kailath (1971), Meyer (1973)) the following: Let

$$Y(t) = \int_0^t s(\tau) d\tau + W(t),$$

with

$$\int_0^T E|s(t)| dt < \infty, E[W(t) - W(\tau)z(\tau)] = 0, \quad t > \tau.$$

Then, the process $E(\cdot)$ defined as

$$E(t) = Y(t) - \int_0^t \hat{s}(\tau) d\tau$$

where

$$\hat{s}(t) \triangleq E[s(t)F\{y(\tau), \tau \leq t\}]$$

is also a Wiener process w.r.t. the (nested) family of sigma fields $\{F\{Y(\tau), \tau \leq t\}\}$. The main idea of the proof is to show first that $E(\cdot)$ is a martingale with respect to these sigma fields, and then to show that $E(\cdot)$ and $W(\cdot)$ have the same 'quadratic variation' (again a concept introduced by Wiener). Then a theorem of Levy's gives the result. This is a nice result, since the process $y(\cdot)$ might be much more complicated than $E(\cdot)$; it shows the power of the assumption of additive white noise. Now in the linear case, results from the theory of integral equations enable us to show that (Kailath (1968, 1972))

$$F\{E(\tau), \tau \leq t\} = F\{Y(\tau), \tau \leq t\}, 0 \leq t \leq T$$

so that the process $\{Y(\cdot)\}$ and $\{E(\cdot)\}$ are replaceable each by the other, without any loss of information. As mentioned earlier, this was the idea behind the innovations approach to the Wiener filter (Bode-Shannon (1950), Zadeh-Ragazzini (1950)); in the nonstationary finite-time case, the above result allows for a similar approach to the Kalman filter and several related problems (Kailath (1970), Davis (1977)).

Therefore an important question is under what conditions this equality of sigma fields holds in the general case. The problem turned out to be quite difficult (Benes (1976)) and only after attempts by several researchers, did Allinger and Mitter (1981) succeed in proving the equality for the case where $s(\cdot)$ and $W(\cdot)$ are independent of each other and $\int_0^T E[s(t)]^2 dt < \infty$.

However even without the equivalence, the process $E(\cdot)$ leads to several nice results. One is that even though the sigma fields generated by $E(\cdot)$ and $Y(\cdot)$ may not be equivalent, Fujisaki *et al.* (1972) showed that any function measurable w.r.t. the Y sigma fields can be written as a stochastic integral w.r.t. the Wiener process $R(\cdot)$. This then allows for a simpler description of the nonlinear filtering equations: however as mentioned before, they are not useful for actual computation.

Another application that exploits only the fact that $E(\cdot)$ is a Wiener process is a generalized Cameron-Martin formula for the Radon-Nikodym derivative of the measures P_y and P_w induced by the processes $Y(\cdot)$ and $W(\cdot)$:

$$\frac{dP_y}{dP_w} = \exp \int_0^T \hat{s}(t) dY(t) - \frac{1}{2} \int_0^T |\hat{s}(t)|^2 dt.$$

This expression has useful implications for the problem of detecting the presence or absence of a random signal $s(\cdot)$ in the presence of noise. When the signal $s(\cdot)$ is deterministic (and therefore known *a priori*) $\hat{s}(\cdot) \equiv s(\cdot)$, this is a result of Cameron and Martin (1944). It is an interesting and useful fact that for random $s(\cdot)$ the deterministic formula still applies with the

unavailable random signal $s(\cdot)$ being replaced by the observable least-squares estimate $\hat{s}(\cdot)$. This allows a lot of the insights and results of estimation theory to be carried over to signal detection theory (Kailath (1969), Davis and Andreidakis (1977)). We may remark that the Cameron-Martin formula arose as a theory of 'linear changes of variables' in Wiener space (the space of sample functions of a Wiener process). The generalized Cameron-Martin formula follows from a nonlinear version of this theory introduced in a seminal paper of Girsanov (1960), which has since been much studied and extended.

9. Concluding remarks

This has been an account of some of the ways in which Norbert Wiener's work and ideas have influenced several engineering developments. The key ideas were his emphasis of the statistical nature of the communication process and his introductions of the use of optimization criteria into system design. I should hasten to add that many other notable researchers (Shannon, Rice, Tukey, Bellman, Pontryagin, Kalman, to name just a few) had major roles in the post-1942 story. Finally, Wiener's own specific mathematical contributions to mathematical engineering are too numerous to cover in a simple article. Here I have described, in a very sketchy way and with some focus on things I know best, some of the wide range of ideas and techniques stimulated by Wiener's work on prediction and filtering.

Heat shock proteins – Role in thermotolerance of crop plants

C. Viswanathan and Renu Khanna-Chopra

Water Technology Centre, Indian Agricultural Research Institute, New Delhi 110 012, India

Thermotolerance is required in crop plants in order to maintain productivity under heat stress. At the cellular level, thermotolerance is linked with the induction of heat shock proteins (HSPs), a response conserved from prokaryotes to eukaryotes. HSPs belong to six families and each family has several members, of which only a few may be involved in acquired thermotolerance. Molecular approaches may help to assign specific role to HSPs involved in thermotolerance. Thermotolerant genotypes show adaptations at various levels of organization besides showing qualitative and quantitative differences in HSPs as compared to the thermosensitive genotypes. In future, HSPs and enzymes with broader thermal kinetic windows may be the desired selection criteria at molecular level for breeding thermotolerant crop plants.

AGRICULTURE production must continue to meet the demands of the growing population. In the past decades agricultural production increased due to higher yields and by bringing more land under agricultural production. The scarcity of productive agricultural land may force us to grow agricultural crops in harsher environments. Temperature is an important environmental factor affecting crop productivity. Crops have high productivity when grown in temperatures optimum for various growth and metabolic processes. Temperatures higher than the optimum decrease both the rate and duration of metabolic processes and thus decrease the yield.

Being poikilothermic, plants have to keep their temperatures below ambient through transpiration. In water-limited environments, transpiration is reduced, thus plants experience both water and high temperature stress. Howard¹ remarked that, 'Wheat production in India is a gamble in temperature'. Even today, the wheat season in North India is limited by temperature at both ends of the crop growth. It has been observed that for every one degree rise in mean temperature over the range of 12.2–27.5°C the wheat yield is reduced by 4%. Therefore, to sustain the agricultural production it is necessary to breed varieties which are tolerant to high temperature stress. Further, the current estimates of global warming predict an increase of 0.5°C annual

mean temperature by 1995–2005, 1.5°C by 2050 and 3°C by 2050–2100 AD. These changes in mean values of temperature may be accompanied by high frequencies of extreme levels of heat and moisture.

Thus, it is necessary to understand the physiological and molecular basis of high temperature stress tolerance. In this review, we focus on role of heat shock proteins in high temperature stress tolerance and productivity of crop plants.

Heat shock proteins

Heat stress (5–10°C above the normal growing temperature of organism) induces expression of specific gene families called heat shock genes (*hsps*), which lead to the synthesis of a new set of proteins called heat shock proteins (HSPs). After Tissieres *et al.*² demonstrated for the first time that heat-induced chromosomal puffing of *Drosophila melanogaster* was accompanied by the high level expression of an unique set of proteins called heat shock proteins, HSPs have been found in every organism in which it has been sought from unicellular prokaryotes to highly evolved complex multicellular organisms including *Homo sapiens*. In fact, HSP induction upon heat shock is a highly conserved universal genetic response among organisms from Antarctic algae to archaeobacteria^{3–5}.

The heat shock response of all organisms shares the following common features:

1. Immediately following the heat shock, a new set of unique HSPs are synthesized from newly-transcribed mRNAs.
2. Heat treatments, which induce HSP synthesis, also lead to acquired thermotolerance, i.e. the ability of an organism to withstand a normally lethal temperature if it is first given a heat shock at non-lethal temperature.

Heat shock proteins are classified into two broad categories based on their expression. The heat shock-inducible proteins are called HSPs while the HSP homologues, which are expressed in the cell during normal cell growth and differentiation, are called Heat Shock Cognates (HSCs). Based on their molecular

REVIEW ARTICLES

Table 1. HSP families

Family	Expression	Location	Functions
HSP110			
HSP104-yeast	Heat inducible	Cytosol	Thermotolerance,
HSP101-soybean		Nucleus	EtOH tolerance
- <i>Arabidopsis</i>			
-rice	ABA		
Casinoytic protease			
(CLP)-pea, tomato			
- <i>Arabidopsis</i>			
ERD 1- <i>Arabidopsis</i>	Dehydration		
HSP90			
80-90 kDa	Constitutive	Cytosol	
HSP81,82- <i>Arabidopsis</i>	Heat inducible	ER	Chaperone
HSP90 - <i>Brassica</i>		Nucleus	
HSP82-yeast			Thermotolerance essential for viability
HSP70			
Dnak (63-79kDa)	Constitutive	Nucleus	Thermotolerance, negatively regulated hsp expression
HSP70-soybean, maize	Heat inducible	Cytosol	molecular chaperone
HSC70-tomato, pea		Mitochondria, Chloroplast	
SSA, SSB, KAR2-yeast			
HSP60			
53-62 kDa	Constitutive	Nucleus	Molecular chaperone
GroEL homolog	Heat inducible	Chloroplast	
HSP60-maize	Developmental		
HSP20			
10-30 kDa	Heat inducible	Nucleus	Protection of organelle macromolecules
HSP20-soybean	Constitutive	Cytosol	
wheat, carrot	Developmental	Mitochondria	
petunia		Chloroplast	
<i>Vigna sinensis</i>	Heat inducible	Chloroplast	
Ubiquitin			
8.5 kDa-maize	Constitutive	Cytosol	Proteolysis
-wheat	Heat inducible		
- <i>Arabidopsis</i>			

weight, HSPs (and HSCs) are grouped into six families (Table 1). The high molecular weight HSPs predominate in prokaryotes, yeast and animals. In higher plants the low molecular weight HSPs predominate and may play crucial role in heat stress tolerance⁶. All the HSPs are coded by nuclear genome except a HSP20 family member of *Vigna sinensis*, which is coded by chloroplast genome.⁷

Mechanism of protection

The role of HSPs during normal cell growth and development in the proper folding of polypeptides, formation

of multimeric enzyme complexes and transport of proteins to the proper site/organelle has been well studied⁵. Historically, HSPs are believed to prevent the accumulation of aberrant proteins generated as a result of exposure to high temperature or other forms of stresses. Evidences available so far indicate that HSPs protect proteins from denaturation, salvage the denatured proteins and target the aberrant proteins for proteolysis. In soybean, both high and low molecular weight HSPs protected soluble proteins from heat denaturation⁸ and the degree of protection showed dose-dependent character and did not require any additional energy⁹. Repair of heat damaged/denatured proteins is essential for both

survival and recovery from heat stress. HSP104 of yeast, which is essential for survival under heat stress, functions by reactivation of heat-damaged proteins. Thus HSP104 repaired the denatured luciferase to the control level *in vivo* within two hours¹⁰. This function of HSP has been confirmed *in vitro*, but needs to be confirmed *in vivo* in higher plants. Similarly, HSP60 from etiolated *Avena sativa* seedlings stimulated the refolding of chemically-denatured phytochrome to a photoactive form within an hour. The reactivation required additional energy as ATP¹¹. Proteolysis of denatured proteins is another strategy, used by cells to prevent accumulation of denatured proteins. Ubiquitins which target the damaged proteins for proteolysis are coded by multigene family¹² and show heat induction¹³ in higher plants. (In wheat (*T. aestivum* L. cv. Len), heat stress elevated the levels of ubiquitin-protein conjugates, induced HSP synthesis and elevated degradation of soluble proteins.) These results indicate that ubiquitin targets the denatured proteins for proteolysis under heat stress¹³. The protection of damaged proteins is less energy dependent while proteolysis is more energy dependent.

Regulation of HSP expression

The remarkable conservation of heat-stress response from prokaryotes to eukaryotes includes not only the structure and function of the HSPs but also the control of their stress-dependent expression. The environmental stimuli that induce *hsps* other than heat stress are toxic metals, inhibitors of energy metabolism, amino acid analogues, etc. Although HSP inducers are bewildering in their variety¹⁴⁻¹⁷, many of them have in common the capacity to cause protein denaturation. Hightower¹⁸ suggested that the accumulation of denatured or abnormally-folded proteins in cells initiated a stress response and the stress proteins might somehow facilitate the identification and removal of denatured proteins. This proposal was confirmed when Ananthan *et al.*¹⁹ showed that injecting denatured proteins into living cells was sufficient to induce *hsp* genes in eukaryotes.

In eukaryotes, the induction of transcription of *hsps* is mediated by pre-existing transcription factors, the heat shock factors (HSF). HSFs are transacting factors, which upon activation bind to heat shock promoter elements (HSEs) at the 5' upstream end of *hsps*, and induce the *hsp* expression^{5,20}. The binding motif of HSE is composed of 5 bp (nGAAn) blocks in alternating orientation and at least three units are required for stable binding²¹. In higher organisms, binding of HSF to HSE is heat stress inducible^{22,23} and requires conversion from a latent monomer to an active trimer²⁰. HSF genes have been isolated from the yeast (*Saccharomyces cerevisiae* K. lactis), higher plants (tomato and *Arabidopsis*), fruit

fly, chicken, mouse and man. HSFs have two highly-conserved regions: an NH₂-terminal DNA binding domain of ~100 amino acids and an adjacent trimerization domain containing 3 hydrophobic heptad repeats, leu zippers. For the higher eukaryotes there is a fourth zipper domain near COOH-terminus that appears to interact directly with the more NH₂-terminal Leu zippers array to prevent trimerization under non-stress condition⁵. HSF is encoded by a single gene in yeast and *Drosophila* and by three genes in tomato²³. Using tomato HSF genes (*hsfs*) as heterologous probes, *Arabidopsis hsf1* has been cloned²⁴. Sequence comparison of *hsf* genes from different species demonstrates a strong conservation but only in their DNA binding and oligomerization domains. Out of three *hsfs* of tomato, *hsf8* is constitutively expressed, while *hsf24* and *hsf30* are induced by heat stress²⁵. The *hsf1* is also constitutively expressed but the level is increased to two to threefold upon heat shock.

HSF activation may also involve cellular factors as intermediary sensors to regulate activity of HSFs under non-stress conditions. HSFs are maintained in monomeric form through transient interaction with HSP70 and/or other HSPs which are constitutive. During heat shock, due to the availability of denatured/misfolded proteins, which are substrate for HSPs, they release HSFs and bind to denatured proteins. These free HSFs can then form trimers to bind HSEs^{5,20}. Thus in cells, a homeostatic mechanism involving the free level of HSPs (=HSP70) provides a thermometer for reacting to temperature changes. HSFs which are expressed during normal temperature and heat stress are different and heat-induced phosphorylation of some HSFs suggests that other kinds of activation of HSFs also occur in cell²⁶. Species-specific expression of *hsps* may be regulated by the specific upstream sequences on the *hsp* genes, as in case of barley *hsp17* (ref. 27).

Role of HSPs in thermotolerance of higher plants

The induction of HSPs is characteristic of an emergency response, i.e. they are extremely rapid and very strong. For example, in *Glycine max* seedlings, *hsp* mRNAs are observed within 5 min of heat shock, and up to 20,000 fold induction of HSPs occurs²⁸. Secondly, the induction temperature reflects stress conditions for the organism (Table 2).

The plant species adapted to temperate environment (soybean, maize, pea and wheat) begin to synthesize HSPs when tissue temperature exceeds 32–33°C (ref. 29). Thus the HSP-inducing temperature of these organisms reflects the thermal characteristic of the environment in which the organisms are growing. Under field conditions, soil water deficit enhanced midday canopy

Table 2. *hsp* induction temperature of organisms

Organism HSP maximum	Growth temperature optimum (°C)	Induction temperature (°C)
I. Archaeobacteria		
Extreme thermophile <i>Pyrodichim occultum</i>	102	108
II. Prokaryote: <i>E. coli</i>	38	42
III. Eukaryotes		
1. Arctic fishes	0	5-10
2. <i>Drosophila</i>	25	33-38
3. Birds	25-35	43-45
4. Mammals		45
5. Snow fungus <i>Fusarium nivale</i>	12	25
6. Antarctic algae <i>Plocamium cartilagineum</i>	0	5
7. Yeast <i>Saccharomyces cervisiae</i>	25-28	37
8. Higher plants		
a) <i>Lolium temulentum</i>	25-30	35
b) <i>Triticum</i> sp.	20-25	32-40
c) <i>Glycine max</i>	28	40
d) <i>Sorghum bicolor</i>	35	43-45
e) Maize	35	43-45
f) <i>Pennisetum glaucum</i>	35	45
g) Tomato	25	35-37
h) Cotton	30	40
i) <i>Arabidopsis thaliana</i>	22	35

temperature of 40°C induced HSPs in cotton³⁰. Even in irrigated wheat, HSPs were expressed in the field condition when the flag leaf temperature reached 32-35°C and HSP expression was correlated with the thermotolerance³¹. Hence HSPs are expressed in these organisms, when their temperature increases above the normal, rather than at a universal temperature threshold. The kinetics of HSP induction and acquired thermotolerance are tightly coupled and highly conserved among the evolutionarily diverse organisms. Moreover, HSPs show high similarity in nucleotide and amino acid sequences among eukaryotes, and in some cases also with prokaryotes. These evolutionary conservations clearly suggest the importance of HSPs in heat stress tolerance of organisms.

Correlation between HSP expression and thermotolerance

Acquired thermotolerance is correlated with HSP synthesis in many organisms, including higher plants^{3,29,32}. Using etiolated soybean seedlings Lin *et al.*³³ have shown that the rate of synthesis of low molecular weight HSPs is correlated with acquired thermotolerance. Soybean seedlings are able to acquire thermotolerance by a pre-treatment of 2 h at 40°C or 10 min at 45°C followed by 2 h at 25°C. Thus, the pre-heat shock temperature which induced HSP synthesis resulted in the tolerance of

seedlings at 45°C, 2 h heat shock. The 40°C pre-heat shock not only induced the HSP synthesis in soybean seedlings, but also resulted in the localization and stable association of HSPs with cell organelle fractions (nuclei, mitochondria and ribosome). Similarly in other crops like wheat³⁴⁻³⁷, sorghum, pearl millet^{38,39}, and maize⁴⁰, the seedling thermotolerance at otherwise lethal temperature is correlated with the kinetics of HSP synthesis. These studies strongly suggest that the accumulation of HSPs is important for protection from thermal killing. If so, the next question arises, whether the quantity of HSPs or the quality of HSPs is important in providing thermotolerance. *Triticum monococcum* L cultivars, M₃ and M₉, which differ in thermotolerance, did not differ in the quality of HSP induced at 37°C. But Northern analysis using HSP cDNAs as probes revealed that the tolerant genotype M₃ was able to accumulate higher steady state mRNA level of 16.9, 26 and 70 kDa HSPs than the heat susceptible M₉ during heat hardening period⁴¹.

In *Triticum aestivum*, the heat tolerant variety Mustang maintained its cell viability up to 80% when pre-heat shocked (at 34°C) wheat leaves were exposed to 50°C for 1 h, while the susceptible genotype Sturdy could maintain only 40% cell viability. Mustang also maintained its capacity to synthesize a small subunit of Rubisco at 34°C, while Sturdy could not. Two-dimensional gel electrophoretic analysis revealed the presence of three unique HSPs (16, 17 and 26 kDa) in

Mustang³⁵. In case of maize also, the drought and heat-tolerant genotype ZPBL1304 synthesized an unique 42 kDa HSP, which was absent in susceptible line ZPL389 (ref. 40). Thus, not only are the HSP synthesis and acquired thermotolerance tightly coupled, but also the intraspecific differences in quantity, quality and the rate of accumulation of HSPs are highly correlated with thermotolerance.

Cellular localization of HSPs: Heat shock dependent

The positive correlation between acquisition of thermotolerance and HSPs appears to depend not only upon synthesis of HSPs but also on their cellular localization^{33,42,43}. In soybean, heat hardening, which induced seedling thermotolerance, also induced synthesis and selective localization of HSPs. Cell fractionation studies revealed that the low molecular weight 15–18 kDa HSPs selectively localized and associated with nuclei, mitochondria and ribosomes, a lesser amount of 68–70 and 90 kDa HSPs localized in these organelles. While some 22–24 kDa HSPs remained soluble in cytosol, they remained organelle associated during a chase at 40°C, but dissociated gradually during a chase at 28°C. If again 10 min heat shock at 45°C was given, the localization occurred within 15 min. Arsenite-induced HSPs did not localize at 28°C, but they became organelle associated during subsequent heat stress³³.

Similarly, pea HSP22 was strongly associated with chloroplast thylakoids when the temperature was raised above 38°C, at high light intensities^{44–46}. Studies conducted in *Chlamydomonas* showed association of LMW HSP with PS II which protected the PS II from photo-inhibition⁴⁷. In higher plants too, the localization and association of HSPs with organelle demonstrated the protective role of HSPs during heat stress. In soybean seedlings, at 38°C, all HSPs were synthesized, but their organelle localization occurred at 42.5°C. The 15–18 kD HSP and 70 kDa HSP were associated with mitochondria at 42.5°C and dissociated during 4 h recovery period at 20°C. This association protected the mitochondrial phosphorylation at non-permissive temperatures⁴⁸.

Cross tolerance and HSPs

HSPs are induced by many other stresses such as ethanol, malonate, arsenite³³, amino acid analogues⁴⁹, abscisic acid^{50–52}, drought stress⁵¹, wounding⁵⁰, γ -rays⁵³ and cold⁵⁴. If thermotolerance is a direct result of HSP synthesis, then the other treatments which induce HSP synthesis should also induce thermotolerance. Arsenite induced HSP synthesis at 28°C in soybean and was able to provide thermotolerance to the seedlings³³. Also, the

arsenite-induced HSPs showed heat-induced localization and association with organelles. In 40-day-old seedlings of sorghum and pearl millet, arsenite (100 μ M) and malonate (25 mM) induced HSPs synthesis comparable to that of 45°C heat hardening induced HSPs, which also gave thermal protection to the protein synthesis and seedling growth at 50°C³⁸. Ethanol (4%, 6%) which was able to induce HSP synthesis and provide cross tolerance in yeast⁵⁵, was unable to induce either HSPs or thermotolerance in sorghum and pearl millet³⁸. Cell free fractions (soluble proteins) isolated from control and ABA treated cells of *Bromus inermis* Leyss showed different temperature tolerance in temperature-induced protein coagulation assay. Addition of 50 μ g (5%) of ABA induced heat stable proteins and decreased the rate of heat-induced coagulation of cell free fractions *in vitro*⁵⁰. Thus, it seems logical to conclude that HSPs must be playing an important role in thermal protection of higher plants.

Genetic complementation

Not only the heat shock response, but also the HSPs themselves and their regulation of expression is highly conserved among evolutionarily diverse organisms^{20,29}. HSP101 of *Arabidopsis* and soybean show 43% identity to *Saccharomyces cerevisiae* HSP104 at the amino acid level. The conservation of structure and mode of expression suggests that the functionality must have also been conserved. To test this possibility, yeast HSP104 mutants, which did not acquire thermotolerance⁵⁶, were transformed with *Arabidopsis thaliana* hsp101 and soybean HSP101 gene. Higher plant HSP101 is undetectable in yeast (transformed with *Arabidopsis thaliana* hsp101/*Glycine max* hsp101) in the absence of heat stress, but accumulated to high levels during exposure to high temperature. Both *Arabidopsis thaliana* HSP101 and *Glycine max* HSP101 are able to complement the thermotolerance defect caused by HSP104 gene mutation^{57,58}. HSP104 in yeast functions in thermotolerance by promoting the reactivation of heat-damaged proteins after high temperature stress¹⁰. Since higher plant HSP101 was able to complement the thermotolerance deficiency of hsp104 mutant yeast strain, it seems plant HSP104 is able to functionally complement the HSP104 of yeast. Therefore, it appears that HSP104 provides thermotolerance to higher plants in a manner which is functionally similar to that of yeast HSP104.

Molecular biology approaches

Molecular biological approaches were used to prove the role of HSPs in thermal stress tolerance in several organisms. HSP mutations in yeast⁵⁶ and *E. coli*⁵⁹ resulted in temperature sensitivity. Complementation of the yeast

hsp104 mutation by either yeast or higher plant HSP101 resulted in restoration of acquired thermotolerance^{57,58}. Over-expression of HSP70 in *D. melanogaster* resulted in faster acquisition of thermotolerance⁶⁰. Similarly selection of thermotolerant cell lines of Chinese hamster fibroblast cell showed high level expression of HSP70 (ref. 61). Competitive inhibition at transcriptional level of *hsp70* gene in Chinese hamster ovary (CHO) cells reduced the heat-induced expression of *hsp* by at least 90%, which resulted in elevated thermosensitivity⁶². Expression of *hsp27* gene from metallothionein-regulated promoter in CHO cells, conferred metal regulated thermotolerance⁶³. Affinity purified monoclonal antibodies to HSP70 when introduced into human fibroblasts by microinjection impaired heat-induced translocation of HSP70 into nucleus after mild heat shock and rendered the cells thermosensitive⁶⁴. *D. melanogaster* and mammalian cells transformed with *hsp70* and *hsp90* antisense genes respectively, accumulated HSP70 at a slower rate and showed reduced thermotolerance^{60,65}.

These studies conclusively prove that some or other kind of HSP is involved in the protection of cells under high temperature stress. These kinds of molecular approaches have been limiting in higher plants because of

1. Existence of *hsp* multigene families showing high homology among the members.
2. Polyploidy nature of several plant species.
3. Lack of knowledge of roles of each HSP family under normal/stress environment.

However, Schöffl⁶⁶ suggested two gene manipulation strategies for HSP analysis in higher plants which includes:

a) Selection of cells and plants with constitutively repressed gene for which antisense mRNA approach appears to be more promising because within the members of a family ~90% homology is present. Hence, it should be possible to repress the expression of all family members by a temperature dependently transcribed antisense mRNA of single gene.

b) Generation of plants that overexpress the desired HSPs, which will be useful to examine the biological effect of protein dosage, protein structure and changed specificity under thermal stress.

Already studies have been initiated to study the regulation of HSP expression in higher plant using 1) GUS gene fused with *hsp* promoter⁶⁷. 2) Soybean *hsp70* fused with *Drosophila hsp70* promoter⁶⁸, which showed regulated expression of HSPs environmentally and developmentally. Efforts have also been made to over-express/to inhibit synthesis by antisense mRNA approach. The tobacco transgenic tobacco plants developed by soybean HSP17.6 fused with cauliflower mosaic virus 35S promoter expressed constitutively to the level comparable

to that of heat induction⁶⁹. However, upon heat shock in the transgenic tobacco plants Gm HSP 17.6 was inhibited which indicated that CaMV35S promoter was not transcriptionally competent under heat stress. In antisense transgenic tobacco (soybean *hsp17.6* fused with cauliflower mosaic virus 35S promoter in the antisense orientation) the level of expression was very low, the reasons being the long distance of the inverted gene from its promoter site and lack of a suitable 3' termination signal of transcription⁶⁹.

Developmental expression of HSPs

All the cells/tissues so far examined are capable of synthesizing HSPs in response to heat shocks, except germinating pollen^{70,71} and pre-torpedo stage of very early embryo development⁷². So, in all other stages of plant development, HSPs are expressed in response to heat stress. The question then asked is, are HSPs developmentally regulated in the absence of heat stress? Studies from eukaryotes including plants clearly indicate that there is, in fact, a tissue and developmental specificity in the expression of HSPs. Expression of HSPs in optimal growth environments occurs in flowers, pods and seeds of pulses⁷³, sepals, filaments and styles of transgenic *P_{hsp18.2}::Gus* marker gene *Arabidopsis thaliana* plants⁶⁸ and during embryogenesis⁷⁴⁻⁷⁷. HSC70 is shown to express during vegetative and reproductive stages of tomato^{75,76}. HSPs did not express in germinating pollen and early imbibing embryos although both were very thermotolerant, the preformed HSPs may be playing a potential role in providing thermotolerance. HSC are stored in mature pollen⁷⁴ and seeds, probably to ensure survival in anticipation of potential heat stress. The involvement of HSPs in temperature stress tolerance and normal development has to be further tested.

HSP and crop productivity under stress

Crop productivity or grain yield is the result of a series of processes involving growth and development spread over the entire life span of the crop. These processes are supported by and regulate the various metabolic processes at the cellular level. Grain yield represents the dry matter partitioned towards grains and hence is directly related to the total dry matter accumulation by the crop. Dry matter accumulated over a period of time is related to the net photosynthesis rate and the total leaf area. High grain yield is the culmination of complementary relationship between 'source' (photosynthate availability) and 'sink' (grain no. × grain weight)⁷⁸.

High temperature stress causes accelerated plant development and consequently reduces both vegetative growth and grain yield⁷⁹. At the cellular level, heat stress results in metabolic disturbances, depletion of

respiratory substrates and reduction of photosynthetic activity. It may also cause denaturation of proteins, inactivation of enzymes and damage to cellular structures. Heat stress is especially deleterious during grain filling stage when it inhibits starch accumulation leading to grain weight decrease⁸⁰.

Breeding high temperature-tolerant varieties of crops is an important component of breeding programmes. Stability in grain yield in stress environment is an acceptable criterion for expressing the relative thermotolerance of varieties and species. Stability analysis helps in identifying contrasting genotypes and species which provide ideal material for analysing the basis of thermotolerance at various levels of organization. Infact the response of plants to high temperature has been identified as a two-tier response. For a temperate crop such as wheat, increasing temperatures in the range of 18–32°C constitute high temperature stress while temperatures above 32–40°C constitute the heat shock range. The two ranges of temperature evoke distinct responses which differ considerably.

Although the deleterious effects of heat stress on wheat productivity were known and emphasized in the beginning of the century^{1,81}, in India and Australia, emphasis on understanding the mechanism underlying heat tolerance is only recent. It is realized that a complex character like heat tolerance with respect to grain yield may not be linked to a single metabolic process. Plants have a multitude of mechanisms which help them to survive and propagate under high temperature stress. These include heat stress avoidance and heat tolerance mechanisms.

The heat avoidance mechanisms enable the plants to keep their temperature lower than ambient, through mechanisms such as

- 1) Transpirational cooling (in spring wheat genotypes, canopy temperature depression was significantly and positively correlated with yield stability under unirrigated conditions⁸²).
- 2) Differences in reflection of solar radiation through increase in leaf hairiness and wax deposition.
- 3) Leaf shading of tissues that are sensitive to sun burn.

The heat tolerance mechanisms operate in situations when tissue temperature is higher and yet plant functions are maintained. These include

- 1) Biomembrane saturation^{83,84}.
- 2) Synthesis of enzymes and isozymes with broad thermal kinetic windows and protective enzymes such as glutathion reductase, peroxidase, catalase, super oxide dismutase, etc.
- 3) Protection of biomembrances, molecules, organelles and maintaining their function, where HSPs may play a very crucial role.

Over 7 million ha of wheat cultivated in the subtropics suffers from heat stress. In central and southern parts of India, wheat suffers from heat stress at both the ends of crop growth. Sorghum and pearl millet also suffer in Rajasthan where during seed germination the soil temperature ranges from 50 to 60°C. High temperature stress causes yield reduction through accelerated phasic development, accelerated senescence, reduction in photosynthesis, increase in respiration (maintenance respiration) and inhibition of metabolic process of grain development such as starch synthesis. Rice also suffers from high temperature stress in tropical areas. When temperature rises from 24°C to 28°C, quantum efficiency of photosynthesis is decreased by 5%, while the rate of respiration increased by 30%. Thus the dark respiration is a primary limiting factor for energy fixation by canopies in tropical rice cultivation.

The amount of solar energy harvested during crop growth depends on the leaf area, which depends on the proper germination, seedling establishment and tillering/branching. High temperature stress drastically reduced germination in wheat^{34,85}, sorghum, pearl millet³⁸ and maize⁸⁶. In all these crops, thermotolerance of germination and seedling growth, and the kinetics of HSP synthesis were positively correlated^{33,34,36,38,41}. In cereals, leaf and shoot growth occurs from meristems situated near the soil surface and thus high soil surface temperature may have adverse effect on tiller and leaf production. In Central India, where soil temperature reaches 35°C to 40°C at the time of sowing, wheat variety Hindi 62 performs better than high yielding varieties because of its ability to germinate under heat stress and maintenance of tiller production. Hindi 62 which has the capacity to germinate at high temperatures exhibits high amylase activity at 30°C compared to a susceptible variety⁸⁷. Also, in seedling stage Hindi 62 showed higher and faster accumulation of hsp16.9, hsp17.3 and hsp26.4 transcripts at 35, 40 and 45°C compared to susceptible varieties (Viswanathan and Khanna-Chopra, unpublished). Thus, it seems logical to conclude that HSPs may be an important component of stress tolerance during germination and seedling establishment.

After seedling establishment the biomass accumulation depends on two important processes, i.e. i) photosynthesis and ii) respiration (growth and maintenance). Photosynthesis is highly susceptible to high temperature stress. Photosynthate availability decides sink size and in turn crop yield. In C₃ plants, quantum yield decreased by 22% when the temperature increased from 20°C to 35°C. Net photosynthesis in wheat started to decline beyond 28°C. In photosynthesis PS II is the most susceptible component to high temperature stress⁸⁸. Heat shock induced integration of 22–25 kDa HSPs into thylakoid membranes in pea and localized onto the stroma of chloroplast^{3,29}. In *Chlamydomonas* HSPs 22 and 29 kDa were localized into grana lamellae during heat

stress and protected Photosystem II from photoinhibition⁴⁷. Rubisco, the most abundant protein on earth, is also susceptible to high temperatures. In wheat the synthesis of Rubisco SSU is inhibited at 34°C in the susceptible wheat cv. Sturdy, while cv. Mustang was able to maintain Rubisco SSU synthesis and was correlated with synthesis of unique HSPs⁴⁰. Although in higher plants, existence of several chloroplast-specific HSPs has been demonstrated in *Pisum sativum*, *Phaseolus vulgaris*, *Arabidopsis thaliana*, *Vigna sinensis*, *Zea mays* and wheat, their correlation with protection of photosynthesis has yet to be demonstrated. Thus, HSPs may be an important component of thermotolerance of photochemical as well as biochemical components of photosynthesis. Under high temperature stress, cells need more energy to protect/repair the heat damaged macromolecules, biomembranes, organelles and for acclimation/adaptive reactions, i.e. the maintenance respiration need will be more under heat stress. Heat stress drastically reduces mitochondrial respiration. This may lead to metabolic aberrations, even if it happens for 2–3 hours in the midday, and to low crop productivity. *Phaseolus acutifolius* had maintained its mitochondrial efficiency at 32°C and thus plant growth, while *P. vulgaris* did not maintain its mitochondrial efficiency and thus reduced plant growth⁸⁹. The direct correlation between HSPs synthesis, its localization in mitochondria and maintenance of mitochondrial efficiency at 42.5°C had been demonstrated in soybean seedlings⁴⁸. Thus, HSPs appear to play a vital role in protecting mitochondrial respiration of crop plants.

At molecular level by protecting and repairing the macromolecules (enzymes, carrier proteins, ion channels, etc.) and by targetting the denatured macromolecules for proteolysis, HSPs may play a vital role in thermotolerance of all the metabolic processes, throughout the crop growth period. Increased solute leakage is another detrimental effect caused by heat stress at organelle and cellular levels. Under heat stress the membrane thermostability is an important component of thermotolerance and is highly correlated with yield stability⁸². By selecting genotypes for high membrane thermostability, yield increase had been achieved under heat stress⁹⁰. Increased solute leakage is attributable to loss of membrane integrity through lipid phase transitions and the effect on membrane proteins. Leakage of substances (amino acids, sugars, ions) into the incubation medium from soybean seedlings at 45°C was prevented if the seedlings were pretreated at 40°C, 2 h and during this process a 15 kDa HSP associated with the plasmamembrane, appeared to play a role in the protection of membrane proteins during heat stress⁹¹. The other component of membrane thermostability is through membrane lipid saturation, relatively a long-term adaptive process. Therefore, it appears logical to conclude that HSPs may be one of the essential compo-

nents of thermotolerance mechanism of crop plants and crop productivity under heat stress. If HSP is to be used as a selection criterion in breeding for thermotolerance, its genetics and heritability must be known. Efforts to link HSP accumulation with QTLs have not given very promising results⁹². Hence more studies are needed in this direction.

Future prospects

The role of HSPs in thermotolerance has been questioned in higher plants^{93,94}, yeast⁹⁵ and *E. coli*⁹⁶. Plants have at least six *hsp* families with several members in each family. These *hsps* show differential expression under stress and development, hence all the HSPs may not be required for stress tolerance in all the tissues. Can thermotolerance of crop plants be increased by altering the *hsp* expression? Studies to answer this question are stymied because the following questions also remain to be answered.

1. Identification and assignment of the role in stress tolerance of each HSP *in vivo*.
2. In stressed cells, what decides the damaged protein to choose the salvage or proteolysis pathway?
3. How is the expression/action of HSF controlled under stress and development?

To engineer plants with temperature stress tolerance, *hsp* expression may become an important approach along with alteration in thermal kinetic windows of key enzymes⁹⁷ and membrane lipid unsaturation. Further, HSPs can be used as a selection criterion in breeding programmes aimed at thermotolerance.

Slower-chemical or faster-electrical signalling under stress in plants: Is it the hare and tortoise story of a slower signal winning the race?

G. Rekha, L. Sudarshana*, T. G. Prasad, Mahesh J. Kulkarni and V. R. Sashidhar[†]

Department of Biochemistry* and Department of Crop Physiology, University of Agricultural Sciences, GKVK, Bangalore 560 065, India

In stress physiology, one of the controversies related to root to shoot communication under stress, has been whether electrical signals from roots precede the chemical signal, represented by the predominant positive signal, abscisic acid (ABA) which accumulates up to 50 fold in the roots and xylem sap of stressed plants. Electric signals can be produced and transmitted to the shoots 18 cm away from the roots in 25 s when an osmotic stress is given to the roots. However a recent finding that ABA applied to the roots itself can generate electrical signals has only fuelled or exacerbated the controversy. In this paper

we have attempted to analyse the relative merits of a faster but apparently short distance intense signal, with the slower chemical signals. We have critically assessed what appears to be a 'deliberate strategy' of the plants to spatially separate two diverse but equally effective signals. The question we pose in this paper is, can a chemical signal still precede an electrical signal? If true, the plant must devise a different way to release an already available sequestered chemical signal. This is akin to resolving the classical dilemma of what comes first the chicken or the egg.

MAN has been concerned with plant stress adaptations since the first pre-historic cave dweller selected seed for propagation from plants that performed better than their neighbours. Physical and biochemical responses of plants to environmental stresses have been studied for over a century and a great mass of data is available. These responses embrace a fascinating spectrum of adaptation, ranging from the survival of the unicellular

algae *Dunaliella* in the harsh saline waters of the dead sea of Israel through a process called osmoregulation¹, to the survival of *Opuntia*, the common cactus, in the Californian desert when the temperature of its shoot reaches 65°C, i.e. 17° above the air temperature².

Although these two examples represent plant adaptations to a saline and high temperature stress respectively, the predominant abiotic stress affecting plant growth and development is by far drought or water deficits. This concern is reflected by the number of

[†]For correspondence.

books devoted exclusively to the review of plant adaptations to water deficit³⁻⁶. These adaptations are classified as drought avoidance or escape, dehydration postponement, and dehydration tolerance. In the second category, the study of stomatal behaviour under stress should rank first amongst all the traits which have been studied during the last four decades particularly after the advent of porometry (a system designed to determine the stomatal resistance to gas exchange as a reflection of the rate of water loss from leaves) in the late sixties. As Rascke⁷, one of the pioneers in stomatal physiology, put it, 'Land plants are in a perpetual dilemma throughout their lives: Assimilation of CO₂ from the atmosphere requires intensive gas exchange and the prevention of excessive water demands that gas exchange be kept low'. Plants have learnt through evolution to strike some compromise between these two opposing objectives. Inherent in this strategy of compromise is to develop a system of communication, which will signal the stomata to restrict opening to avoid excessive water loss. In this system a 'message' synthesized by the roots which is the first to sense the water deficit, leaves the root, uses the xylem as a conduit, reaches the stomata and restricts water loss as a classical 'first line of defence'.

In the last decade there has been considerable interest in this novel signalling mechanism in different stresses; drought flooding and saline stresses⁸⁻¹⁰.

Several investigators including the authors of this paper, have been interested in root to shoot signalling under water stress. These signals can be either the slower chemical signal or the amazingly fast electrical signals. Recently this novel root to shoot communication has found a place in the second category of drought resistance mechanisms, that is those associated with postponement of stress¹¹ because these mechanisms are primarily meant to be a 'first line of defence' against stress. Thus a new area of plant stress research has emerged, targeting distress signal communication in plants. Whichever the signal, chemical or electrical, the consensus reached was that using this communication system, the shoots system of the plants have found an incredibly simple way to 'sense' perturbations in the soil environment, well before the shoot itself experienced it. However no consensus has been reached on the basic issue of which signal is more effective; the electrical (also called action potentials) signal or the chemical signal.

The latter has received more attention if the number of reviews during the last five years is any indication¹²⁻¹⁵. The exponents of the chemical signal have essentially used three systems

(a) Split-root systems, with half the roots in wet soil and the other half in dry soil¹⁶.

(b) Long soil columns with the upper roots in the top dry soil and the lower roots in wet soil, initially¹⁷.

(c) A balancing pressure given to the entire root to counter balance the decreasing water potential of shoots¹⁸.

All these had one thing in common, i.e. the whole root or a part of the root system was in dry soil, while the water status of the shoots was similar to that of non-stressed controls. Any change in a physiological process (either stomatal conductance or leaf expansion) can therefore be directly attributed to the production of a chemical signal produced by the loss of turgor of that part of the root system in dry soil. This signal was transported to the xylem and subsequently sent up to the epidermis of the leaf. Immunological quantification of the signal in the epidermis has shown convincingly that it is the signal arriving at the epidermis from the roots which causes the initial restriction of the stomatal opening¹⁶. This early warning signal coming from just a few roots which are the first to dry (in the natural field situation the top 10-15 cm of the soil profile is also the first to dry) is called the 'first line of defence'¹⁹ as it helps to conserve water by reducing transpiration (restricting stomatal opening) and transpiration area (decrease in leaf expansion) so that some water is available at later stages of growth. Such a 'strategy' therefore enables the plant to balance its size with the availability of water.

The nature of chemical signal has received a lot of attention and has been reviewed thrice¹³⁻¹⁵ during the last three years, with the stress hormone ABA receiving primary attention as the predominant positive or accumulating signal. Levels of this hormone have been shown to increase up to 50 fold in the xylem sap¹⁹⁻²¹, enroute to the shoots.

The electric or action potential has received more attention *vis-à-vis* the 'touch me not' syndrome in *mimosa*^{22,23} since the pioneering work of Sir J. C. Bose²⁴ in 1913. Only recently were elegant experiments conducted to show that these faster signals (speed of transmission 7-14 mm/s) can be equally effective as a 'first line of defence' in distress signal communication under stress. Hebbar *et al.*²⁵ were able to show quite convincingly that when a sudden or snap osmotic stress was applied to the roots of sunflower, an electric signal originating in the roots reached the shoot in 25 s and manifested itself ultimately as a decrease in the stomatal conductance (the first line of defense). In another recent work, action potential was also shown to be involved in wound-induced signalling system of plants²⁶. But taking the electric signalling work of Hebbar *et al.*²⁵ (Figure 1) under osmotic stress as a representative example and comparing it with any one of the examples of chemical signals; (say that of the Zhang and the Davies group¹⁹ or our own work²⁰), one realizes that it becomes extremely difficult to analyse the relative merits of either of these signals because of the following reasons.

Figure 1. Influence of action or electrical potentials on stomatal or physiological processes under osmotic stress. (A) Effect of osmotic stress on surface electrical potential at the shoot apex of sunflower seedling. *a* = pattern of electric potential in control, *b* = pattern of electrical potential in response to osmotic stress. (B) Changes in stomatal resistance in control and PEG (25% w/v in Hoagland solution) treated sunflower seedlings with time. (after Hebbar *et al.*²⁵)

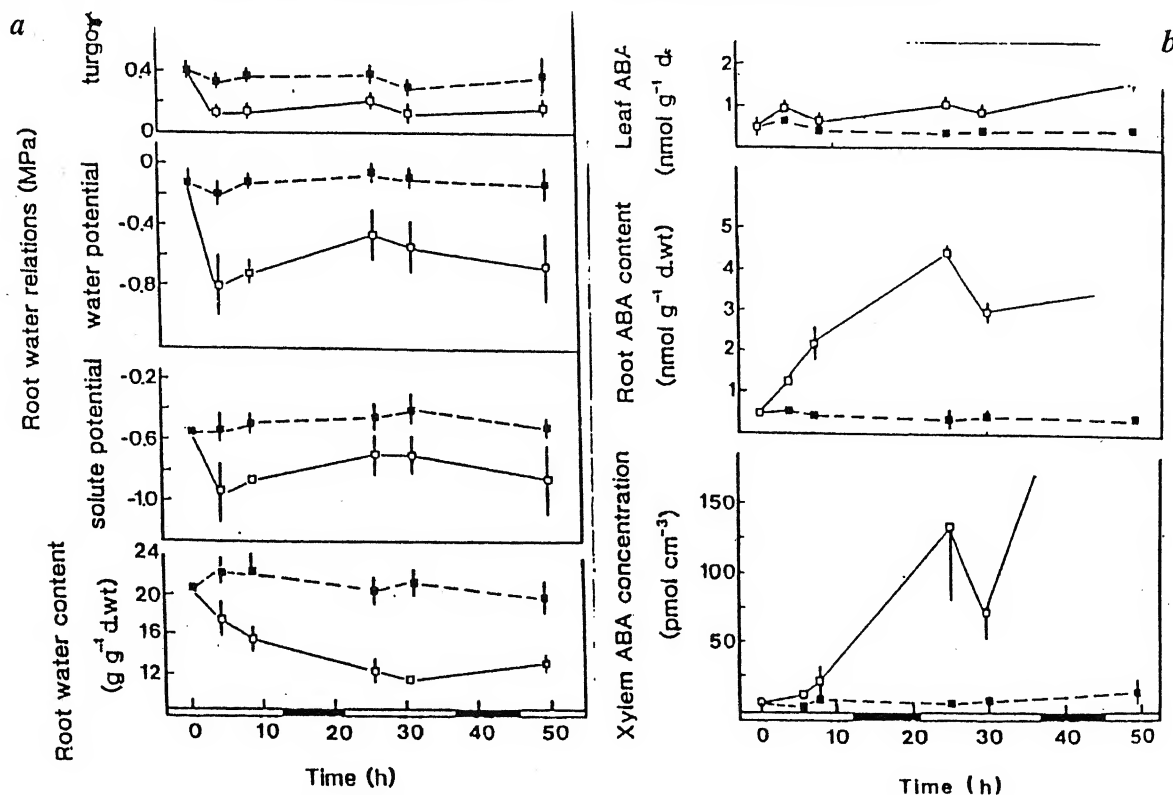

Figure 2 *a, b*. Influence of chemical signal on physiological process under water deficits simulated in the vertical split root system. *a*, Water relations of roots of *Helianthus* plants which protrude from soil, through the base of the pot. Roots in the nutrient solution after time 0 (controls, ■). Roots in moist air after a brief period of air drying (treatment, □). Each point is the mean ($n = 3$) value with \pm s.d. bars. *b*, The ABA concentration in leaves, roots and xylem sap of control *Helianthus* plants (■) and in plants where protruding roots were dried (treatment, □). Points are means of $3 \pm$ s.d. Root data shown are for protruding roots. (after Neales *et al.*¹⁹)

(a) Hebbar's work involved a drastic osmotic stress, and therefore would be expected to convey the action potential in a few seconds.

(b) Our own work reported earlier or that of the Davies group involves a slow dehydration of the roots either naturally in a soil column or an artificial one where the lower, free hanging roots are allowed to lose water. This process even if accelerated involves a time frame of hours. For example, Neales *et al.*¹⁹ utilizing this system showed a decrease in conductance of 30–40% in maize plants through a chemical signal ABA, in 5 h, by slow dehydration of the lower free hanging roots (Figure 2).

In all these cases, the root–water relations are mandatory (see Figure 2 of Neales *et al.*, 1989) and is useful to compare the extent of the ABA signal from different laboratories. A PEG stress, on the other hand, besides being a drastic stress has several shortcomings.

(a) Water relations of the root is extremely difficult to determine.

(b) The roots attain equilibrium with the water potential of the osmoticum only after several hours.

(c) Long before that the action potential has already been transmitted to the shoot.

Figure 3. Changes in water relation, stomatal conductance and chemical signal ABA on rapid dehydration of free hanging roots in a vertical split system.

Figure 4. The vertical split root system developed by the Zhang and Davies group¹⁶ (upper roots grow in wet soil while lower roots protrude through the base of the pot and hang freely. These roots can be dehydrated either rapidly (outdoors) or slowly (suspended in a humid cabinet).

(d) Comparisons between work of different workers are near impossible as equilibrium time varies with the morphology of the roots of different species.

How then does one analyse the relative merits of an electric signal and a chemical signal? The fact that the former is faster is obvious. Why then does a plant spend so much energy on producing a second chemical signal? The answer could hinge on resolving an entirely different issue.

(a) Is an electric signal only capable of being transmitted up to short distances (most work on these signals deals with distances of 18–20 cm, rarely more)? In fact Zawadzki²⁷ clearly showed the limitations of an electric signal with regard to the distance. The action potential, he observed, has three major limitations.

(a) Occurs only when the stem was electrically stimulated, not the leaves and roots,

(b) Does not spread to the neighbouring internode,

(c) Gets extinguished in the region of the stem apex and root neck.

The first one of course has been quite convincingly disproved by Hebbar's work, but the second and third suggest that an electric signal could fulfill only the initial need of transmitting a fast signal up to a short distance. Later a greater more intense long range signalling mechanism could operate (a chemical signal has also been shown to operate in the tree seedlings of apple²⁸).

Resolving this issue has, however, become more complicated by the recent observation of Fromm²⁹ that the application of ABA (a chemical signal) was itself able to elicit an electric signal that travelled to the leaves within 2.5 seconds. The classical dilemma is what comes first – the chicken or the egg or to use a more scientific jargon, can a chemical signal precede an electrical signal. But since ABA accumulation has been shown to require transcription³⁰, it is obvious that a chemical signal cannot be visualized in a time frame of seconds but only in hours. Very recently we specifically conducted experiments to resolve at least partly this question, i.e. can a time frame for a chemical signal to be sent from roots to shoot, be reduced at least to minutes. We fixed 30 min as the minimum time required for ABA accumulation after transcription and translation and artificially accelerated the process of dehydration of the roots using the split root system developed by Zhang and Davies¹⁶ (Figures 3 and 4). When the lower free-hanging roots were dehydrated quickly and made to lose 6% of their fresh weight in less than 30 minutes, ABA increase in roots and xylem sap was still not significantly different from the control levels at 0 hours. Only a 15% loss in fresh weight in 1 h caused a significant increase in ABA which apparently in turn caused a significant decrease in conductance (Figure 3). Our data corroborates closely with that of Neales *et al.*¹⁹ who also showed that a 20% drop in root water content in 5 h resulted in a significant increase in ABA. What we have done is merely shifted the time frame to 1 h instead of the 5 h by accelerating the process of dehydration. Once the required threshold loss in turgor is achieved, then current models are adequate to explain the mechanism of accumulation at the cellular and molecular level³¹.

It is impossible to visualize a time frame of seconds for a chemical signal like ABA to be detected in the roots even if it was caused merely by release of already sequestered ABA from organelles³² due to ion gradients and not ABA synthesis. Since the latter requires transcription, one would have to visualize a time frame of at least 15–30 minutes for synthesis of ABA, even if one were to accelerate the dehydration process by whatever means to make the roots reach the threshold loss of turgor in just a few minutes.

Keeping aside these arguments, how does one explain Fromm's observation of an electrical signal being produced by ABA application to the roots in seconds. Clearly more work needs to be done at cellular levels using sophisticated neurophysiological techniques like

the patch clamp, while giving credit to Sir J. C. Bose for pioneering its use in the beginning of this century, exactly eighty-three years ago. Until then we would have to be satisfied merely by disagreeing with the moral of the hare and tortoise story, i.e. there is no way the tortoise (chemical signal) can win. The hare (electrical signal) will win all the time.

RESEARCH ACCOUNT

Application of ion–solvent interaction parameter in interpreting the kinetic profiles of Diels–Alder reactions and thermal stability of DNA duplexes in ionic solutions

Anil Kumar

Physical Chemistry Division, National Chemical Laboratory, Pune 411 008, India

Rate enhancement in Diels–Alder reactions and thermal stability of a DNA duplex at several ionic concentrations are the main issues addressed in this account. The proposed quantity, internal pressure of a salt–solvent, which is also a measure of electrostriction effect together with the activation volumes of reactions can describe the impressive rate accelerations of the Diels–Alder reactions carried out in salt solutions. Similarly, obviation of high pressure conditions for the synthesis of organic molecules is described. More importantly, the application of the concept of internal pressure and volume has demonstrated that the thermal stability of several DNA duplexes in the presence of ions can be explained. The pressure dependence of thermal stabilities at constant ionic concentrations is linear in nature. The correlations exposed for the DNA duplexes have strong potential to unravel the forces responsible in stabilizing a DNA duplex or the formation of a duplex from its complementary strands.

MOLECULAR interactions of a solvent molecule with nonionic and ionic solutes play vital roles in governing the static and dynamic behaviour of a system. Various thermodynamic, kinetic and other solution properties of the system represent specific behaviour of these molecules in a given environment. With regard to solvents,

Mother Nature discovered the secrets of water in different biological and other natural processes, whereas nonaqueous solvents continued to gain importance in a variety of man-made processes.

Considering the importance of the solute–solvent interactions in several processes, we have very recently embarked on a programme to investigate their role in controlling the kinetic profiles of the organic reactions, like Diels–Alder (D–A) reactions^{1,2} and the association and dissociation processes involved in nucleic acids³. Some of these results along with the futuristic views have been described here.

Definition of solute–solvent interactions in the present context

Cohesion among molecules in the liquid phase results from intermolecular forces. These forces, in general, include hydrogen bonding, dipole–dipole, multipolar, dispersion interactions and also interactions emerging from the repulsion between two molecules. The cohesion due to intermolecular forces gives rise to a 'pressure' which is experienced by the solvent molecules. This term for pure solvent was initially proposed by Hildebrand and Scott⁴ and subsequently supported by the equation of state⁵. A liquid undergoing a small, iso-

RESEARCH ACCOUNT

thermal volume expansion does work against the cohesive forces which causes a change in the internal energy, U . The function $(\partial U/\partial V)_T$ is called internal pressure of a liquid. According to Hildebrand and Scott⁴, definition of internal pressure for a non-polar liquid can be transformed into that for polar by a specific factor indicating the polarity of a solvent. Thus, the internal pressure for a non-polar liquid differs from that of a polar. For instance, the internal pressure values for water and *n*-hexane are noted to be 166.4 MPa and 235.7 MPa, respectively.

Internal pressure changes upon the addition of a solute. Such addition of a solute, particularly of ionic nature, brings about a great change in the cohesion of a solvent. While some solutes like NaCl, KCl, etc. enhance the internal pressure of the solvent, salts like of guanidinium decrease it. As seen later, this phenomenon in solution can prove to be a vital tool in unraveling the origins of forces involved in some organic reactions and more importantly, the thermal stabilities of nucleic acids.

Due to the high electric field associated with an ion, water molecules are oriented around it, causing a local collapse of the bulk water structure. Since water molecules are more firmly packed around an ion than in bulk water, the net volume of the system decreases in the region. This process, called electrostriction (ES), is thus a result of ion-water interactions and it mainly depends on the charge and the radius of an ion, and the changes in local dielectric constant around the ion^{6,7}. The ES effect can be described in terms of internal pressure. Internal pressure, P_i of a solution can be estimated from the experimental quantities by the expression $P_i = \alpha T/\beta$; where α and β are the coefficient of thermal expansion and isothermal compressibility, respectively at a temperature T . Both α and β can be measured from experiments on volumetric properties. In the cases where these values are not readily available, the scaled particle theory⁸ can be used. We have employed this theory for the solute and solvent of different sizes⁹. This theory yields P_i to within $\pm 3\%$, when compared to experimental data. In Table 1, the P_i values for some salts in water are represented by a polynomial equation as a function of the salt concentration, M .

Fascinating observations in the kinetic profiles of D-A reactions

These addition reactions result from the reaction of a diene with dienophile and are useful in synthesizing complex organic molecules. Several years ago, Rideout and Breslow¹⁰ demonstrated the application of pure water as a reaction medium in these reactions. Two exciting outcome of this medium were the impressive enhancement in reaction rates by several order of magni-

Table 1. Parameters of the equation $P_i/\text{MPa} = 166.4 + aM + bM^2 + cM^3$ for a few representative salts in water ($P_{iw} = 166.4$ MPa) as function of M (mole l^{-1})

Salts	a	b	c
NaCl	10.792	61.273	0.532

tudes in the cases where the reaction in other solvents was either not possible or very sluggish. Secondly, the stereoselectivities in the reaction products (endo/exo ratios) could be altered to some extent. Success of the reactions in water prompted the application of 'solute-solvent' additives for altering the kinetic profiles of some very cumbersome reactions. One of these reactions is the synthesis of cantharidin, which was conventionally synthesized under an external ultrahigh pressure of 16–18 kbar or 1.6–1.8 GPa (ref. 11). The use of a reaction medium comprising of lithium perchlorate-diethyl ether (LDPE) led to the synthesis of cantharidin with better yields at atmospheric pressure¹². Conversion of a high pressure reaction to an atmospheric reaction using such additives which are comprised of ionic solutes and water or nonaqueous solvent, proved to be a milestone in

synthetic chemistry. Following this work, several sluggish reactions have been successfully conducted in such media²⁻¹⁴. Similarly, the use of other salts like LiCl, NaCl, etc. in water has further enhanced the reaction rates. On the other hand, salts like guanidinium chloride have retarded the reaction rates. Figure 1 depicts a general picture of variation in the reaction rates of such D-A reactions in the pressure of salt-solvent systems. Examples of some D-A reactions in aqueous as well as in nonaqueous solvents with ionic solutes are mentioned in Table 2. Rate enhancement in aqueous media has been ascribed to several effects like hydrophobic interactions, micellar catalysis, hydrogen bonding and solvent effects. An excellent discussion on these effects has been recently documented¹³⁻¹⁴. One of the most potential explanations to describe the impressive rate enhancements is based upon the Lewis acid catalysis of the reaction.

In short, several other contrasting explanations to describe the origin of forces that are responsible for such effects have been put forward. With due credence to all the explanations, we in our recent work, have attempted to correlate and explain the variations in reaction rates with the help of a bulk property of solution, i.e. internal pressure as shown in the following discussion.

Possible explanations of the reaction profiles of the D-A reactions

First, we examine the reactions in aqueous reaction media. Two situations in this case are pertinent, where the reaction rates of the D-A reactions are increased or decreased by different salt-water systems¹³. Among others, a simple reaction of *N*-ethyl maleimide and anthracene-9-carbinol shows enhancement in rates in presence of aqueous NaCl, NaBr, etc.¹⁵. On the other hand, the rates are decreased by the medium of guanidinium salt. An examination of the P_i values in such salts shows that those reaction media which enhance the rates, also exhibit the increase in internal pressure. The same is true

for the decrease in the rate reactions. It is, thus, possible to correlate the rates with internal pressure for different reactions. In Figure 1 are shown the reaction rates versus P_i for the above reaction in the presence of sodium and guanidinium salts. An excellent linear plot is obtained in this system. Such linear plots between the reaction rates and internal pressures for several other reactions in aqueous environment indicate that the internal pressure can be used as a strong correlating parameter in these reactions. As a matter of fact, the arrangement of water molecules is drastically changed in the presence of salts¹⁶.

This change affects the transition state of a reaction. The increase in internal pressure with increasing concentration of salts like NaCl, NaBr, etc. enhances the ES effect. On the contrary, the ES effect due to the guanidinium salt type decreases with the increase in the ionic concentrations. An important outcome emerging out of such work is the possibility of the role of hydrophobicity¹³.

Both diene and dienophile due to their dislike for water come close enough to react. This hydrophobic effect is further enhanced in the presence of those salts which accelerate the D-A reactions. Obviously, a decrease in hydrophobicity can be considered, when the reaction rates decrease in the presence of salts like those of guanidinium. Similarly, the hydrophobicity increases in the rate enhancing salts¹⁷. We have also noted that the reaction rates also depend upon the size of salt used as a reaction medium. As seen in Figure 1, the reaction rates decrease, if the size of anions increases for the same salt series keeping the cation common. This variation is consistent with the increasing or decreasing hydrophobic effects in the presence of salts and their relations with the reaction rates. These results can also be understood in terms of ion-water interactions.

Though our primary objective in this account is focused on aqueous environment, it is essential to briefly mention ionic interactions in nonaqueous solvents and their implications on the reaction rates. Such interactions, like those available in the lithium salts with diethyl ether, acetone, ethyl acetate, etc. can be used to correlate both the reaction rates and stereoselectivities of the D-A reactions². For obtaining these correlations, activation volume and internal pressure P_i are used to describe the rate data.

Activation volume, an activation parameter is the only appropriate choice for studying a reaction, when pressure of the system is variable. Activation volume (ΔV^\ddagger) data yield valuable information on the kinetics of reaction. The ΔV^\ddagger is defined as the difference of reactant partial volumes and the volume of the transition state. The ΔV^\ddagger can be obtained by the use of liquid phase non-ideality calculations, besides high pressure kinetics¹⁸. In the method used in our work, activity coefficients were deployed to yield liquid phase non-idealities of compo-

Table 2. Some examples of the Diels-Alder reactions promoted by the salt-solvent systems

nents. We used a well-known model known as Universal Functional Group Contribution model abbreviated as UNIFAC¹⁹, where the interactions between cation, anion and their individual and mutual interaction with solvent are explicitly considered by a combination of extended Debye-Huckel equation and interaction energies of nonideality. In a nutshell, both quantities i.e. internal pressure and activation volume offer us excellent correlations with the kinetic profiles. Thus, it is possible to explain why the reaction rates vary with ionic concentrations and why two reactions show different reaction profiles under specific conditions of a reaction medium. In further work, we have also been able to demonstrate the utility of our proposed concept in dealing with the D-A reactions conducted in different pure solvents and their aqueous mixture²⁰. The parameter on which such correlations are based, requires the internal pressure normalized to a polarity scale.

In the foregoing discussion, we noted that the addition reactions like the D-A reaction, which yield impressive rate enhancement in the presence of salt solutions, can be described using an internal pressure term. In essence, enhanced internal pressure together with activation volume of a reaction prove to be of tremendous use in understanding the kinetic accelerations in the D-A reaction in the ionic solutions described above.

With this development in reaction kinetics, it was intriguing to explore the possibility of explaining melting behaviour in nucleic acids. Melting of a nucleic acid, for example, of DNA duplex involves a dissociation process or reaction, which takes place in ionic environment. On the other hand, the formation of a DNA duplex in ionic environment is an association reaction. In the following discussion we shall attempt to examine the dissociation or association reactions in a similar fashion that was used to correlate the kinetic data of Diels-Alder reactions.

Nucleic acids

Effect of various salts

Although both proteins and nucleic acids are particularly prominent among the molecules essential to life, molecular interactions in nucleic acids, particularly DNA will be the sole focus of our discussion. DNA is a very long biomacromolecule composed of a large number of deoxyribonucleotides. A nucleotide consists of three molecular fragments, i.e. sugar, base and phosphate. Interactions to nucleic acids are highly specific and play crucial roles in controlling the transcription, recombination, replication, etc. An important aspect of a DNA molecule which warrants attention is its stability in aqueous ionic media. This stability can be judged by the melting of DNA solution or adding some ionic sub-

stances. The melting temperature, T_m at which a DNA double helix converts into two complementary strands, depends markedly on the base composition, base stacking and the ionic environment in general²¹⁻²⁶. In fact the very formation of the DNA duplex from its complementary single strands is governed by these parameters. It is established both by experiments and theory that DNA molecules are heavily hydrated. Effect of water on the stabilization of DNA helices via hydration, therefore, assumes a vital role in understanding the energetics of DNA.

As a matter of fact, interactions of counter ion Na^+ with the regular lattice of negatively-charged phosphate groups (PO_4^-) of the sugar-phosphate backbone of the DNA helix can change the degree of hydration and contribute to the stability of DNA helices. A valuable contribution in this regard has been made by Manning²⁷, who used a rigorous approach of counterion condensation, where the statistically averaged properties of mobile cloud of counterions tends to neutralize the net electrostatic charge of the nucleic acid. Later, Record *et al.*²¹ utilized the polyion condensation theory of Manning for the analysis of stability of the DNA helices. In their simple treatment, they introduced a concept of thermodynamic binding, defined on the basis of a suitable combination of several ionic effects. These interactions which are electrostatic in nature have been the subject of intense investigation by theoretical methods. The classical methods of analysing these interactions have largely been based on the Debye-Huckel, Gouy-Chapman, Poisson, Poisson-Boltzmann equations, etc. whereas Monte Carlo simulations, molecular and Brownian dynamics are some of the very recent techniques used to understand the role of ions on the stability, structure, dynamics and related properties of DNA²⁸. The resultant equations have been useful in analysing the stability data of DNA helices particularly in the low ionic concentration range. A reference should be made to the work of Troll *et al.*²⁹ in which the effects of permittivity discontinuity at the boundary between aqueous phase and the low dielectric DNA cylinder were studied in order to understand the stability aspects of the DNA helices.

As seen above, several qualitative and quantitative explanations have been put forward to describe the stabilization of the DNA helix in aqueous medium. In our work, we have been primarily concerned to gain insights into the process of formation of a DNA helix from its complementary single strands or the melting of a DNA helix into two complementary single strands in the presence of an ionic atmosphere. For explaining the thermal stability effects, we have preferred to correlate T_m with the process of electrostriction. It seems to us that the electrostriction effects, if expressed in terms of a measurable thermodynamic quantity, can be used to interpret several features of the thermal stability of a

DNA helix, without recourse to much complex mathematics. A quantity useful in the present analysis of thermal stability of DNA helix is the volume change, ΔV , accompanying the transition process. The hydrated DNA consists of two discrete layers representing primary and secondary hydration shells. In fact, the bases in single strands tend to form complementary hydrogen bonding leading to the formation of hydrophobic core in the DNA helix. The phosphate groups lie exposed to water and impart considerable charge density to single strands and to their double helix. The magnitude and sign of ΔV depend upon the base stacking, the degree of hydration, the charge density parameters of both the single complementary strands and duplex, and the electrostriction of the water molecules^{23,24,26,30,31}.

Both the P_i and ΔV parameters can now be utilized to examine the issue of thermal stability of a DNA duplex in different situations.

Thermal stability – Enhancing behaviour

It is established that the thermal stability of the duplex is greatly influenced by salt concentrations²¹. For instance, higher concentrations of NaCl induce greater stabilization of the duplex (higher T_m), as compared to lower T_m noted at low concentrations data of salt. Our calculations of P_i using the most reliable density and compressibility^{32,33} show that P_i of water increases upon the addition of NaCl. Such a variation in P_i can be indicated by the effective internal pressure ΔP_i , as $\Delta P_i = P_i - P_i^w$ where P_i^w is internal pressure of pure water. The term P_i denotes the change in internal pressure of water occurring upon the addition of a salt. The aqueous ionic environment thus remains under high pressure conditions, which are enhanced almost up to the solubility limit of NaCl in water. The transition of a duplex to single strands is reported to be accompanied with the positive volume changes. The possible reasons for the positive ΔV values and their variations with the salt concentrations, observed in the above transition of a duplex can be understood in terms of electrostatic and stacking effects^{34–36}. For instance, in the case of Poly(dA).Poly(dT), the ΔV values are noted to vary from 2.60 to 7.81 cm³ mol⁻¹ in the range of NaCl concentration from 0.02 to 1 M. The ΔP_i value at 1 M is much higher than that at 0.02 M. This high internal pressure suppresses the process of transition of a DNA duplex to single strands since V is positive for the melting process. Thus, in order to obtain transitions at a higher NaCl concentration, a higher temperature needs to be employed. This leads to a higher T_m value which increases with the addition of NaCl. In other words, one may state that the ES or the enhanced P_i resulting from the salt concentrations controls the T_m of a duplex DNA. To illustrate these variations, the relationship between

Figure 2. Relationship between transition temperature T_m and effective internal pressure ΔP_i for the double helix transition. ▲, Poly(dA).Poly(dT); ●, Poly[d(A-T)] Data ref. 36; ▽, Poly(dA).Poly(dT); □, Poly(rA) · Poly(dT); ○, Poly(rA).Poly(rU); △, Poly(rA).Poly(dU) (data Rentzeperis *et al.*²⁵). First data set at high NaCl concentration; All other sets low NaCl range; corresponding salt concentrations are also shown.

T_m and ΔP_i are shown, in Figure 2 for the transitions of several duplexes of Poly(dA).Poly(dT) or the polymers containing AU base pairs in different NaCl concentrations, ranging from low to high, at atmospheric pressure. The duplexes with GC base pairs are known to have higher T_m values owing to lesser hydration and more number of hydrogen bonds as compared to the AT base pairs. In the case of duplexes³⁷ with high GC contents, curves of T_m versus P_i are shown in Figure 3. The shape of the curves is a typical temperature–pressure plot encountered in transitional reaction kinetics. In the case of higher valent salts like MgCl₂, higher values of P_i are obtained as compared to those for NaCl at corresponding concentrations. In general, values of P_i for MgCl₂ are almost three times as high as those for NaCl up to 4 M, as calculated from literature data^{32,33}. Thus, almost the same stability for a given duplex can be obtained using a much lesser concentration of MgCl₂ as compared to a given concentration of NaCl^{21,38–41}. The ES effect enhances when one moves from uni-, multi-valent ionic salts¹⁸ for which the thermodynamic support comes from the activity coefficient data⁴².

Figure 3. Demonstration of relationship between T_m and ΔP_i for the denaturation of *E. coli* (O) and *D. pneumoniae* (Δ) with high GC contents in KCl. The corresponding concentrations are given in ref. 37.

Thermal stability decreasing behaviour

As seen above, thermal stability of a DNA duplex increases by the addition of certain salts like NaCl, KCl, etc. Contrary to the observation, the DNA duplex is destabilized in the presence of some other salts, such as acetates, perchlorates, etc. As a matter of fact, it is the property of a salt or ionic media, which has a strong correlation with the variations in T_m of a duplex. For instance, the T_m values of a duplex in the presence of NaClO_4 , KCNS and CF_3COONa at several ionic concentrations are reported to be decreasing with increasing concentration⁴³. Explanation of this experimental observation can be found out using the concept of negative changes in ΔP_i upon the addition of salts. Values of ΔP_i in such salts can be calculated from the experimental data or theoretical methods. Such cases of decreasing T_m with increasing salt concentrations is demonstrated in Figure 4, where the T_m values for these salts are plotted as a function of ΔP_i . There are two interesting aspects in this case; (i) the ΔP_i values are negative and (ii) the curves are smooth up to high concentrations of salts. An examination of plots reveals that the proposed correlation is applicable even to a situation where the T_m decreased by 60°C. The ΔP_i values for CF_3COONa

Figure 4. Plot of T_m against ΔP_i for denaturation of DNA duplex in the presence of salts. \blacktriangle , NaClO_4 ; O, KCNS; \bullet , CF_3COONa (ref. 47).

demonstrate the salt's capability as the most powerful denaturant out of the three studied. In such cases, the negative, ΔP_i values are the results of the anti-electrostriction effect caused by salts as indicated above. In other words, the difference between the molar volume of a liquid salt, and its partial molar volume tends to become negative. This situation appears to be analogous to one arising out of the salting-in effect. Salts like those shown herein have very large anions that make the charge density smaller than that of water dipole, and thus decreasing the interactions as compared to those among water molecules. This argument is supported by several theoretical calculations⁴⁴.

Both the thermal expansion and isothermal compressibility, i.e. α and β , respectively are responsible for calculating P_i values of a system. In the above examples both the contrasting cases of T_m -enhancing and reducing thus should be examined in terms of the α and β terms. It was noted that the salts which enhance the thermal stability with increasing concentration, exhibit a noticeable increase in the thermal expansion and a decrease in the isothermal compressibility with an increase in salt concentrations. On the other hand, for the T_m decreasing salts, an opposite trend is observed, i.e. an increase in isothermal compressibility dominates the thermal expansion when one moves from a dilute to a concentrated

salt solution. For these salts, one can think that a situation of internal pressure drop over pure water is created due to ion-solvent interactions, which when coupled with positive ΔV values, tends to destabilize the duplex, with the consequent lowering of T_m . This destabilizing effect continues to dominate with the increasing salt concentration. The anionic size in the salts influences the internal pressure drop in such situations.

The T_m values for different duplexes at the same ionic concentration show variations, which can be analysed on the basis of similar arguments. Since the ΔV values for the duplex depend upon several parameters described earlier, the effect of a given NaCl concentration or the thermodynamic internal pressure can easily explain the differences in T_m values for the different duplexes. For example, the ΔV values for the transitions of Poly(dA).Poly(dT) and Poly[d(A-T)] at 0.2 M NaCl concentration are 4.59 and 2.14 $\text{Cm}^3\text{mol}^{-1}$, respectively³⁶. The internal pressure of the medium being the same (~189 MPa) at a fixed NaCl concentration (0.2 M), the transition for Poly(dA).Poly(dT) would, therefore, require a higher temperature than that for Poly[d(A-T)], considering the basic thermodynamic relationship between pressure and volume with respect to the kinetics of two processes. Thus, T_m for Poly(dA).Poly(dT) is higher (73.1°C) than that for Poly[d(A-T)] (64.3°C). Thus, the value of ΔV , an indication of the hydration and other structural properties of any duplex, as described earlier, controls the variation in thermal stability at a definite internal pressure at a given NaCl concentration. Values of ΔV , thus, should be credited due importance in the transition reactions.

Pressure effects

Application of external pressure greatly influences the transition of duplex to single strands³⁶. In general, high pressure has been observed to result in an increase in T_m for several duplex-single strand transitions. The calculations in the present investigation of P_i for NaCl using high pressure data⁴⁵ at each applied external pressure value demonstrate that P_i increases with an increase in the external pressure. Thus, the total internal pressure of the system at a given concentration of NaCl is higher at an elevated external pressure than at atmospheric pressure. This increase in the total internal pressure, coupled with the positive volume of transition, inhibits the transition of duplex to single strands. In order to achieve the transition, therefore, a higher temperature is required when the external pressure is higher than the atmospheric pressure. For explaining our argument, we define two quantities: $T_m^R - 1$, (where T_m^R is the ratio of T_m at any external pressure to that at atmospheric pressure) and $P_i^R - 1$ (with an analogous definition as used for T_m). Some valuable information emerges out of plots

Figure 5. Relative transition temperature at various pressures. $T_m^R - 1$ as a function of relative internal pressures $P_i^R - 1$ at various pressures in several NaCl concentrations. O, 1 M; ●, 0.2 M; Δ, 500 mM; ▽, 200 mM duplex; Poly(dA).Poly(dT), range of external pressure covered 200 MPa; at atmospheric pressure (0.1 MPa) $T_m^R - 1 = P_i^R - 1 = 0$; points in plots are chosen to show extent of linearity, though linearity is observed throughout; experimental data from ref. 36; identical observations for other duplexes also.

(Figure 5) between $T_m^R - 1$ and $P_i^R - 1$ at several NaCl concentrations. For example, in the case of Poly(dA).Poly(dT), for which extensive data are available, the plots $T_m^R - 1$ versus $P_i^R - 1$ are linear at each NaCl concentration in the range from 200 mM to 1 M. The extent of linearity is seen up to 200 MPa with slopes of significant magnitude, suggesting the strong influence of internal pressure on thermal stability. It is, therefore, possible to characterize and correlate the thermal stability of DNA duplexes at several ionic concentrations under elevated external pressure conditions.

An important parameter, as pointed out in the foregoing discussion, is the magnitude and the value of ΔV . Two contributions of prime significance resulting into this property come from the base stacking and electrostatic effects. These effects give rise to negative and positive ΔV in the cases of formation of a duplex and transition of a duplex into two complementary strands, respectively. The base stacking effect originates from dispersion forces and hydrophobic effects, whereas the interactions between Na^+ and PO_4^- of DNA strands yield electrostatic effects. Though the signs of ΔV in the duplexation and the reverse reaction are negative and positive respectively, both positive and negative values are noted for duplexation in some cases. These very small positive values noted at extremely low Na^+ concentration are presumably the result of the combined effect of specific base pairing and the low degree of electrostriction. For example, Rentzeperis *et al.*²⁵ noted

positive ΔV at 16 mM Na^+ for Poly(rA).Poly(rU), which became negative at higher Na^+ concentration of 116 mM. Such variations in sign of ΔV have been described in terms of change in hydration of the DNA duplex as a function of ionic concentration.

Recalling the polyion condensation theory²⁷, thermodynamic binding of counter ion Na^+ with polyion PO_4^- is the major step. First, in presence of a salt, the counterion condenses on the polyion in order to reduce the axial charge density of a strand. This is followed by the second step, in which the remaining unneutralized polyions are shielded (screening effect) by an atmosphere of mobile counterions. It is not yet clear how much difference exists in counterion condensation in single strands and duplex²⁴. In the present approach, internal pressure induced by the salt is a bulk solution property and acts as a driving force for the formation of a duplex from its complementary single strands based upon the volume changes accompanying duplex formation. It appears that both the condensation and screening effects are indirectly accounted for in the internal pressure term of a salt solution. In our recent work, we have noted the magnitudes of both of these effects on the T_m values of the DNA duplexes, where the counterion condensation effects was noted to outcompete the screening effect. Details of these effects in terms of the pressure parameters are being communicated.

Conclusion and futuristic ideas

To summarize, the correlations exposed in the foregoing discussion are significant in many ways. First, the reaction rates and their spectacular enhancement in salt-solvent media can be quantified by a single concept based upon internal pressure and volume changes in reactions. This achievement which is still in the state of infancy needs rigorous testing. Secondly, a plausible explanation can be thought over for obviation of external ultrahigh pressure conditions during the synthesis of a compound. These two major achievements may eventually lead to the preparation of a selection software, which could be of potential use in recommending the reaction conditions to some extent. Thirdly, an alternate explanation is now available to describe the thermal stabilities of DNA duplexes at different ionic concentrations both at ambient and elevated pressures. Fourthly, since the analysis of thermal stabilities of DNA molecules is a radical departure from the presently-available explanations, there exists a new possibility to examine the physical etiology in sea water.

A brief account of the work discussed above, however, does not answer several important questions that a chemist or biochemist is faced with. An issue of both theoretical and industrial importance, which warrants urgent attention of the physico-organic chemists, is to

quantify the kinetic profiles of organic reactions of different types in terms of molecular interactions. Effect of additives, which are observed to alter the reaction rates and stereoselectivities of the products, is being currently investigated in detail.

How do the electrostatic forces or ion-water interactions govern the behaviour and biological functions of a single DNA strand and a triplex? How can we learn *a priori* about the activation parameters for duplex and triplex formation just from the knowledge of available information on the single DNA strands? A systematic study of duplexes made up of Peptide Nucleic Acid (PNA) and DNA as PNA-DNA for their thermal stability looks promising for designing of certain drug molecules following the concept of anti-sense technology. Calculations on these duplexes are yielding some exciting insights into the thermodynamics of nucleic acids, the results of which will be reported elsewhere.

RESEARCH ARTICLE

Electrical resistivity imaging of Mohand Anticline of Siwalik range: A tectonic appraisal

Ch. Sivaji, B. R. Arora*, R. Kalra and A. K. Pandey

Indian Institute of Geomagnetism, Colaba, Bombay 400 005, India

*Present address: Department of Space Geophysics, National Institute of Space Research, Sao Jose dos Campos, Brazil.

The results of a pilot resistivity sounding experiment undertaken in the Siwalik belt and contiguous Indo-Gangetic Foredeep (IGF) are presented and their lithotectonic significance is discussed akin to the Mohand anticlinal structure. The inferred large lateral resistivity contrast near Ganeshpur delineates the concealed Mohand thrust. The observed resistivity doublet is compatible with the transition in the clast-size and clast-matrix ratio of conglomerate

to sandstone. This correspondence provides strong geophysical support to the proposed four stage evolutionary model of the Mohand Siwalik basin on the basis of the facies association and palaeocurrent data. Cyclic pattern of resistivity distribution seen in the Mohand-Sherpur sector of IGF is considered to manifest episodic character of tectonic events in the Himalayan orogeny.

THE Indian Institute of Geomagnetism has been carrying out the natural source electromagnetic investigations in the Himalayas and the adjoining shield region¹⁻³. These studies, employing magnetovariational and magnetotelluric techniques, image the deep crustal structures in terms of electrical conductivity (inverse of resistivity) distribution. The strong dependence of conductivity on

temperature prevailing at deeper depths and the fluid content released and remobilized by the metamorphic and tectonic processes, makes these investigations a sensitive pointer of the geodynamic process controlling seismic and tectonic activity in the collision regime. These visualizations are well illustrated by the noted correlation of the mapped Trans-Himalayan and Garh-

wal Lesser Himalaya conductivity anomalies with the high seismicity zones^{4,5}. With the objective of supplementing information from shallow depths, it was decided to introduce control source deep electrical resistivity surveys. At shallow depths, the resistivity distribution being more sensitive to the state of saturation and/or to the fractured rock fabrics of the medium, the knowledge of resistivity distribution can effectively be used to infer the control of proximal or distal tectonics on the nature of sedimentation in the foredeep basins as well as in the alluvial fan system developed at the base of rising mountain system. We report in this paper the experimental details and results of a pilot resistivity survey undertaken in and around the Mohand structure of Siwalik range, Garhwal Sub-Himalaya.

Tectonic features of the study area and electrical sounding locations

For the resistivity sounding experiment, a section of the Siwalik range bounded between Yamuna and Ganga tear faults was selected. This section of the Siwalik fold belt lying on the southern flank of the Dehradun valley has received much attention from the Earth scientists for its anticlinal structure, Mohand anticline. The gentle NE dipping strata of the Siwalik range here show a sharp reversal of dip on its southern limit, giving the appearance of an anticline with its axis roughly aligned in NW-SE direction. The lithological sequence in the Siwalik range is represented by sandstone/mudstone couplets at the base, followed by multistoried sandstone complex and capped up by boulder conglomerate, respectively classified as Lower, Middle and Upper Siwalik⁶. Due to the anticlinal uplift, the Upper Siwalik in the crest region is extensively eroded, exposing the underlying Middle Siwalik on the SE flank. The Upper Siwalik are exposed on the NE flank abutting against the alluvium deposits of Dehradun valley. On the SE margin, the Siwalik range terminates into the Indo-Gangetic Foredeep (IGF). The contact boundary between the Siwalik range and alluvial deposits of the IGF, regionally called as Main Frontal Thrust or more simply as Himalayan Foothill Boundary (HFB)⁷, is locally referred to as Mohand Thrust. This thrust is inferred to be concealed under the alluvium deposit^{8,9}. The presence of the Mohand Thrust at depth was confirmed by borehole lithology encountered in structural and deep wells drilled by the Oil and Natural Gas Commission (ONGC) to evaluate hydrocarbon prospects of the Siwalik range⁸.

Four Schlumberger electrical soundings were conducted respectively at Kotri, Dharmawala, Ganeshpur and Sherpur (Figure 1) so as to provide maximum possible coverage of Mohand anticline. The first two sounding lines were located respectively on the southern and northern limb of the anticline. The Kotri sounding

line is located some 14 km northwest of Mohand whereas the Dharmawala sounding is on the northeastern flank of the anticline, close to the contact boundary of Upper Siwalik conglomerate sequence with alluvium. Both these sounding lines run parallel to the general NW-SE strike of the Mohand anticline. The Ganeshpur sounding line is located very close to the boundary between the alluvium and Siwalik with sounding line striking across the Mohand thrust. The fourth resistivity sounding line, centered near village Sherpur, was situated deep within the IGF, some 15 km south of Ganeshpur on the Dehradun-Saharanpur road.

The large variations in the range of apparent resistivities observed between Sherpur and Ganeshpur soundings warranted us to conduct axial dipole sounding to locate the lateral inhomogeneity between these locations.

Data acquisition and reduction

The Schlumberger resistivity sounding technique, adopted here, employs a co-linear electrode configuration symmetrically disposed to the central sounding point. A DC current I , in the form of square wave interrupted for the required time intervals through commutator switches, is injected into the ground by means of outer pair of electrodes A and B . The other pair of non-polarizable electrodes, M and N , placed close to the central point, is used to measure the potential difference, ΔV , resulting from the current flow. An apparent resistivity, ρ_a^{10-12} , is given by

$$\rho_a = \frac{\pi[(AB)^2 - (MN)^2] \cdot \frac{\Delta V}{I}}{4MN}$$

Figure 1. Map of study area showing the location of deep resistivity sounding lines on the Dehradun-Saharanpur road, undertaken to image electric resistivity distribution around the Mohand anticlinal structure.

The current electrode separation is increased systematically to achieve progressively deeper penetration. While moving apart the current electrodes in successive observations, the potential electrodes are kept fixed for a large number of the *AB* settings. The change in *MN* spacing is introduced only when the potential drop across the *MN* falls with increasing *AB* separation to a value close to the limiting precision of the receiver unit. This restricted repositioning of the potential electrodes helps to minimize the distortions resulting from the localized near-surface resistivity inhomogeneities. These effects, termed electrode effects¹³, could pose serious problem in the present case as the study region exposes a wide range of geological formations. The ratio of potential and current electrode separation was maintained between 1:5 and 1:10. This choice ensured adequate voltage drop across *MN* for the entire range of *AB*s.

The field measurements were accomplished with the Scintrex Resistivity Sounding equipment, essentially consisting of a current transmitting unit TSQ-4 backed up by 10 kW motor generator and a voltage measuring unit IPR-8. The motor generator generates three phase 210 Volts (AC) with a frequency of 600 Hz. This energy is transformed according to a front panel voltage setting in a large transformer housed in TSQ-4. The resulting AC is then rectified in a rectifier bridge. The commutator switch controls the DC voltage output in the square waveform interrupted at required time intervals. The IPR-8 receiver has a built-in facility to cancel self-potential existing at the potential electrodes. Driving the source current from generator and transmitter, maximum *AB* separation of 6 km was attained.

The apparent resistivity obtained as a function of electrode separation *AB/2* is plotted on the log-log scale to give usual representation of sounding curve. With a suitable choice of geometrical progression of current electrodes, a fairly uniform distribution of points on the sounding curve was obtained. The raw electrical sounding data as recorded at the Sherpur is shown in Figure 2. Often various segments of the sounding curve, each corresponding to a particular *MN* spacing, exhibit slight vertical shift in relation to adjacent branches. This invariably manifests the electrode effect associated with the repositioning of the *MN* electrodes, also due to the lateral inhomogeneities encountered between previous and present *MN* spacing. Since measurements with larger *MN* spacing involve larger volumes, they provide better average information. The shift in adjacent sections of the sounding curve is corrected by vertically shifting the segment of the sounding curve with smaller *MN* spacing so as to provide fit to the section of the sounding curve with larger *MN* spacing^{11,14}. Figure 2 demonstrates such a shift correction applied to the Sherpur sounding data. With these shift corrections, the overall shape of the sounding curve remains unaltered and only such smooth

Figure 2. Plot of apparent resistivity vs electrode separation (*AB/2*) at Sherpur: as reduced from raw data (top) and after correcting (bottom) for electrode effect seen as vertically shifted segments of sounding curve.

sounding curves are used for subsequent interpretation of a 1-D layered structure.

For the two axial dipole soundings conducted, the current electrodes with 2 and 2.8 km separation were kept fixed while the potential electrodes with constant separation of 700 m were successively moved along the axis of current dipole with radial distances varying from 2 to 8 km on either side of the centre of the current dipole. The values of apparent resistivity for each position of potential dipole, calculated using the formula given below, were plotted as a function of radial distance of potential dipole from the central position of current electrodes to depict lateral variation of apparent resistivity along the line of movement.

The apparent resistivity is computed for the axial dipole configuration by the formula

$$\rho_a = \frac{\pi R^3}{AB \cdot MN} \cdot \frac{\Delta V}{I},$$

where *R* is the radial distance from the centre of the current dipole to the centre of potential dipole.

The axial sounding up to a radial distance of 8 km on either side of the Sherpur and Ganeshpur was undertaken with potential electrodes deployed approximately at every 2 km. Figure 3 shows the lateral variation obtained from two axial dipole soundings, the implications of which are discussed in the foregoing sections.

Numerical interpretation of sounding curves

The corrected apparent resistivity sounding curves have been interpreted by two different approaches, viz. the

Figure 3. Plot showing the lateral variation in resistivity as obtained by axial-dipole soundings at Sherpur and Ganeshpur.

Marquardt-Levenburg¹⁵ and Occam's inversion¹⁶. The Marquardt-Levenburg (M-L) formulation interprets the resistivity data in terms of horizontal layer of isotropic resistivity. The method incorporating *a priori* information on the number of layers as well as initial approximations on layers parameters (thickness and resistivity), performs an iterative process to refine the model parameters while minimizing the sum of the squares of residuals between observed and calculated responses. The Occam's inversion, on the other hand, yields a smooth resistivity-depth model minimizing the integrated square of the first or second derivative of resistivity values with respect to the depth. This approach reduces the ambiguity in fixing up the number of layers in the layered-structured model of the Earth.

Figure 4 *a-d* shows the interpreted layered as well as smooth continuous resistivity-depth distribution models for all the four soundings conducted around the Mohand structure. The degree to which these models explain the data is illustrated in Figure 5 *a-d* by superposing the calculated response of the best fitting models, both layered as well as continuous, on the observed sounding data, separately for all profiles. The comparative study of these models revealed that the maximum and minimum in the Occam's model corresponded well with the resistivities of the layers seen as zones of relatively high and low resistivities. Further, the sharp resistivity discontinuities represented by layer boundaries match well with the inflection points between minima and maxima observed in the Occam's model. The correlation between the reduced resistivity models, obtained by the two techniques, provided confidence in the model parameters. Their primary features are summarized below:

Kotri and Dharmawala soundings

The Kotri and Dharmawala soundings, respectively on the southern and northern limb of the Mohand anticline, present a nearly consistent picture. The Kotri sounding with a thin overburden of modest resistivity (70 ohm.m) indicates a high resistivity layer of about 550 ohm.m

Fig. 4

Figure 4 *a-d*. Interpreted layered (solid line) as well as continuous resistivity-depth distribution (broken-line) models for resistivity sounding curves at (a) Kotri, (b) Dharmawala, (c) Ganeshpur and (d) Sherpur. For Ganeshpur, results are based on the interpretation of restricted (dotted line) and full (broken) sounding curve (see text).

Figure 5 *a-d*. Plots showing calculated responses of best fitting layered (solid) and continuous depth-resistivity (broken line) models, shown in Figure 4, to the observed data (hollow circles) at (a) Kotri, (b) Dharmawala, (c) Ganeshpur and (d) Sherpur. For Ganeshpur and Sherpur, the Occam's and ML, inversion fits are overlapping and hence the broken line cannot be shown separately. The dotted line represents ML, fit for the restricted part of the curve indicated by crossed circles.

having an approximate thickness of 30 m (Figure 4a). The interpretation of the Dharmawala sounding indicates near-equivalent resistivity (ranging between 425 and 740 ohm.m) layer at the surface, extending up to the depth of about 90 m (Figure 4b). On both the soundings, this high resistivity layer is underlain by a relatively less resistive layer. The 4th layer on the Kotri profile has resistivity of nearly 90 ohm.m. This layer is not resolved by the Dharmawala sounding. Of the four soundings operated, the Dharmawala sounding is most strongly affected by the electrode effects. This, coupled with high contact resistance at the current electrodes, has greatly reduced the depth penetration of current. The non-detection of the moderately resistive layer at Dharmawala may be the effect of this restricted penetration, although the presence of such a layer cannot be ruled out by the continuously decreasing trend of the sounding curve at large electrode separation.

Sherpur sounding

In marked contrast to the soundings located on the Mohand anticline, the Sherpur sounding profile located only 15 km south of the HFB into the Indo-Gangetic foredeep, is characterized by low resistivities. Here the resistivity-depth distribution, in the upper 1000 m section, is represented by an 8-layered structure (Figure 4d). The resistivity of the individual layers ranges between a narrow range of 17 and 50 ohm.m, a distinct feature being that resistivity distribution alternates between relatively low and high resistivity layers. The layer of lowest resistivity (17 ohm.m) extending from 10 m depth, with a thickness of approximately 40 m, appears to represent the aquifer. The depth of this layer is in good agreement with the depth of the water table as revealed by the existing wells in the vicinity of the sounding.

Ganeshpur sounding

The Ganeshpur sounding, placed close to the HFB, exhibits an H-type curve (Figure 5c), symbolizing the presence of a low resistive layer sandwiched between resistive layers. However, the sounding curve when the electrode separation AB exceeds 100 m, rises very steeply. Both the Occam and $M-L$ inversion schemes fail to yield a single model providing match for the complete sounding curve (Figure 5c), especially the steeply rising segment. The last segment of the sounding curve will be asymptotic to a line rising at an angle 45° when the lowermost layer is an insulator^{10,12}. However, the observed slope of the experimental sounding curve at Ganeshpur is more than 45° which cannot be explained even by the insulated bottom layer. Hence, this may be visualized as a diagnostic of the presence of

large lateral electrical resistivity contrast at shallow depth along the sounding line. The interpretation of the Ganeshpur sounding curve up to an electrode separation of 100 m by the $M-L$ algorithm, indicated that this section of the sounding curve is compatible with a top resistive layer of 200–300 ohm.m underlain by a low-resistivity layer of 20 ohm.m with an approximate thickness of 33 m extending from the 30 m depth. Assigning these values to a 3-layer model, with only the resistivity of the infinite third layer as a free parameter, the $M-L$ algorithm was made to search by iterative process the resistivity which could provide the closest fit to the rising part of the Sherpur sounding curve. It was found that even when the bottom layer attains a value of the order of 20,000–25,000 ohm.m, the overall fit is not satisfactory and also the match to the first section of the sounding curve is seriously distorted (see Figure 5c). This exercise demonstrated that even a near-insulating substratum at a shallow depth of 60–70 m is not consistent with observations, providing further credence to the hypothesis of large lateral resistivity inhomogeneity. It can be surmised that as the current with increasing current electrode separations tends to penetrate to the depth of the discontinuity, the capacitor-like behaviour of the electrical inhomogeneity tends to drain away the electrical energy (R. J. Sporry, personal communication), resulting in the steep rise of sounding curve after certain threshold of the electrode separation.

It is noteworthy that estimated depth of low resistivity zone (20 ohm.m), obtained by modelling the curtailed sounding curve, agrees well with the water level in a single well located only a few meters away from the sounding centre. Comparison with Sherpur model suggests that aquifer located at 10 m depth deepens to a depth of 30 m near Ganeshpur.

Axial dipole sounding

The results of the axial soundings provide independent confirmation of the lateral resistivity inhomogeneity, a little north of Ganeshpur. The examination of lateral variation plot of resistivity in Figure 3, as estimated from the axial dipole sounding centered at the Ganeshpur, indicates that apparent resistivity on the north-east part is more than 1000 ohm.m as compared to the apparent resistivity of 200–300 ohm.m on the SW part. The axial dipole sounding results centered at the Sherpur revealed uniform value between 30 and 40 ohm.m on either side. These results indicate that near-homogeneous resistivity distribution in the IGF tends to be progressively inhomogeneous as the HFB is reached, with HFB marking zone of sharp resistivity contrast. The deduced lateral resistivity distribution shows good semblance with the exposed lithology of the area. The alluvium-covered region of the IGF is marked by low

RESEARCH ARTICLE

and laterally uniform resistivity whereas the transitional and high-resistivity zones respectively match the pebble mixed alluvium and boulder sequence of the region.

Geological and tectonic bearings

The results of the present resistivity sounding experiment indicate that Mohand Thrust, marked by large lateral resistivity contrast, is located in close proximity to the centre of Ganeshpur sounding. The thrust is indicated to be concealed approximately at a depth of about 40–50 m. Due to the known sensitivity of control source electrical method to resolve resistive structure⁴, the electrical resistivity soundings elsewhere on the Mohand anticline have been able to divide upper pile of sedimentary sequence into a multiple layer sequence. Figure 6 summarizes the results of resistivity soundings in the form a geological cross-section corresponding to shallow depths. The picture of deeper section is adapted from Raiverman *et al.*⁷.

In agreement with the exposed lithology, the top resistive layer (~550 ohm.m) at Dharmawala is shown to correspond with the boulder-bearing sequence of the Upper Siwalik. Extending the analogy, the second resistive layer at Kotri with similar resistivity character is also identified in Figure 6 as boulder dominated conglomerate sequence. Both at Dharmawala and Kotri, this layer is underlain by a relatively lower resistivity

(200 ohm.m) layer. Making in-depth examination of the stratigraphic sections in and around Mohand Siwalik, Kumar and Ghosh⁶ identified four distinct facies association occurring vertically upward as A (sandstone-mudstone), B (sandstone), C (sandstone-conglomerate) and D (conglomerate) the facies association C and D occurring mostly in the Upper Siwalik.

They observed that facies association C is characterized by stratified conglomerate with clast-ratio determined by 30–50% of conglomerate and 40–60% of sandstone. The facies association C gradually passes upward into poorly-imbricated conglomerate sequence in which conglomerate:sandstone ratio changes to 70:30. The clast size also varies from 10–25 cm in facies association C to 25–40 cm in association D. It is interesting to note that resistivity changes observed between resistive doublet at Dharmawala and Kotri are compatible with this transition in the clast-size and the clast-matrix ratio, the upper resistive and underlying relatively less resistive layers respectively representing formations dominated by facies D and C.

Clearly, the ability of the control source electrical method to sub-divide the Upper Siwalik sequence into two distinct layers, arising due to lithological change, can be considered as geophysical support to the four-stage evolution model of Mohand Siwalik basin, proposed by Kumar and Ghosh⁶, with two stages of sedimentation occurring during Upper Siwalik.

At Kotri, this resistive doublet is sandwiched between moderately resistive layers of 70–150 ohm.m. These resistivities are typical of sandstone¹⁷ and are interpreted as representing the sandstone sequence of Middle Siwalik. While the lower layer may mark the Middle Siwalik sequence brought close to surface by compressional forces responsible for anticlinal structure, the top moderately-resistive layer is considered to denote the debris derived from the erosion of Middle Siwalik exposed near the crest of anticlinal structure. Further south, near Ganeshpur, the contact between the concealed resistive Upper Siwalik and alluvium deposit may provide the kind of lateral resistivity contrast mapped by Ganeshpur sounding and axial dipole resistivity surveys. Compressional stresses associated with anticlinal folding may also cause weak flexing of the basement in the immediate vicinity of the southern limb of the anticline and may account for the deepening of the water-bearing sedimentary column as compared to the Sherpur. The subsequent filling of this basin-like structure with the boulders brought down by rising Mohand anticline may provide surface cover, seen here as a surfacial resistive (200 ohm.m) layer near Ganeshpur, concealing the contact between Siwalik and alluvium. Intermixing with the channelized or braided river deposits may lower the resistivity of this boulder sequence as compared to the Upper Siwalik boulder conglomerates seen on the limbs of the anticline.

Figure 6. Schematic geological cross-section across the Mohand anticlinal structure, incorporating features of electrical resistivity distribution estimated from the present study. The vertical scale for shallow section is highly exaggerated but depths of mapped interfaces at each of the sounding sites are shown. The deeper section is adapted from Raiverman *et al.*⁷.

The most interesting feature of the resistivity–depth distribution at Sherpur is the repetition of high and low resistivity couplet. Since the development and nature of sedimentation in the foredeep basin is largely caused and constrained by the tectonic history of the orogen, it is tempting to relate their cyclic distribution of resistivity to the episodic tectonism in the evolution of the Himalaya. The high resistivity layer may be visualized as coarse-grained sedimentary formation due to the rapid tectonic impulses. Superimposed on this is the slow sedimentation during a long quiescent period. The slow sedimentation results in fine-grained rock formations symbolizing the low resistive layers. Further, Bhattacharya and Misra¹⁸ conclude that during most of the middle Siwalik times, the sands were being deposited by streams due to the floods at repeated intervals. They have also visualized that the Upper Siwaliks were deposited under the proglacial conditions in the Mohand area by streams originating from melt waters at the ice front of mountain glaciers. Sinha⁹ pointed out that the sediments of the Siwalik of Mohand were derived from some mobile belt occurring towards east and northeast and consisted of igneous and metamorphic rocks of the Himalayan belt. This mobility, a series of episodic tectonic events, is a manifestation of the general uplift of the Himalaya during the post-Oligocene periods¹⁹.

The relatively low resistivities of all the layers in the IGF as compared to the Siwaliks may be due to the moist conditions prevailing in the foredeep. However, the alternative resistivity highs and lows can be effectively correlated to the episodic tectonic events in the Himalayan belt, if a comprehensive study on the integrated geological and geophysical data is attempted in this sector of Indo-Gangetic Foredeep.

Conclusions

A pilot electrical resistivity survey in and around the Mohand structure has unambiguously located the Mohand thrust. Elsewhere the mapped resistivity distribution is compatible with the lithology and has been helpful in constraining the geological cross-section of the Mohand structure at shallow depths.

The top Upper Siwalik sequence on the NE flank is seen as a resistive doublet. Similar doublet embedded between relatively less resistive layers is identified on the SW flank.

This might warrant that during the anticlinal upliftment, Upper Siwalik sequence may not have been com-

pletely eroded on the SW flank. The exposed sandstone sequence on this flank may simply be the debris of eroded Middle Siwalik from the crest region beneath which lies the normal Upper and Middle Siwalik sequence.

The cyclic distribution of resistivity at Sherpur may be visualized as manifestation of the episodic tectonism.

Interstratified low-Ti and high-Ti volcanics in arc-related Khairagarh Group of Central India

Deepanker Asthana, Manas R. Dash,
Anil M. Pophare and Sunil K. Khare

Department of Applied Geology, Indian School of Mines, Dhanbad
826 004, India

We report here the petrotextonic implications of interstratified low-Ti and high-Ti volcanics in the Khairagarh metabasalts of Sitagota Syncline, Central India. The low-Ti volcanics have higher CaO/TiO_2 , $\text{Al}_2\text{O}_3/\text{TiO}_2$ ratios and LILE (?), LREE, Zr, Hf, and Cr concentration and distinct negative Eu anomalies, and lower FeO^T/MgO , P, V, Sc, HREE than high-Ti volcanics. Although low-Ti and high-Ti volcanics are both arc-related tholeiites, they are not related to each other by crystal fractionation and/or crustal contamination processes. They represent different degrees of partial melting of heterogeneous mantle source under different subduction fluxes, $\text{P}_{\text{H}_2\text{O}}$ and fO_2 conditions.

INTERSTRATIFIED low-Ti and high-Ti volcanics are a characteristic feature of arc-related volcanics globally¹⁻⁴. They have also been reported from many ophiolites⁵. Recently, several geochemical studies have suggested that the younger Khairagarh volcanics of the Dongargarh Supergroup have an arc-related tholeiitic affinity⁶⁻⁸. We report here for the first time, the occurrence of two chemically coherent geochemical groups of interstratified volcanics from the Early Proterozoic (~2.1 Ga) (ref. 23) Sitagota and Mangikhuta Metabasalts of Central India: one higher in TiO_2 (> 0.7 Wt.%) and the other, subtly but distinctly lower in TiO_2

(< 0.7 Wt.%). We suggest the occurrence of similar low-Ti and high-Ti volcanics from other parts of the Khairagarh volcanics, albeit with different minor elemental geochemical characters^{7,9,10} (Figure 1). These observations have important petrotextonic implications for the role of 'subduction-related processes' in the evolution of the Central Indian craton in particular, and the nature of Early Proterozoic global tectonics, in general.

The low-Ti and high-Ti volcanics reported in this communication are fine- to medium-grained metabasalts. Overall, they have retained their relict textures that includes subvolcanitic, subophitic to ophitic and porphyritic types. However, except for relict clinopyroxenes, all other magmatic phases have been replaced by secondary mineral assemblages during alteration(s) and prehnite-pumpellyite grades of metamorphism. Petrography reveals that olivine (?) was followed by clinopyroxene and plagioclase as fractionating phases. The magmatic clinopyroxenes are augites, in both low-Ti and high-Ti volcanics and paradoxically have overall similar chemistry, including their overall Ti contents but with different Ti/Al ratios.

Representative analyses of primitive low-Ti and high-Ti volcanics are given in Table 1. Samples were analysed at NGRI, Hyderabad by XRF and ICP-MS. Analytical techniques, accuracy and precision of the analyses are given elsewhere^{11,12}. The low-Ti and high-Ti volcanics are rather primitive by island-arc standards, in terms of high MgO, Cr and low Al_2O_3 contents. The basaltic (SiO_2 < 52 wt.%) to basaltic andesites (SiO_2 : 52 to 55 wt.%) of the low-Ti volcanics have high MgO (~12 to 7 wt.%) and Cr (~850 to 250 ppm), whereas high-Ti basalts (excluding an anomalous basaltic andesite) have MgO between 8.4 wt.% and 7.2 wt.% and Cr between ~350 ppm and 85 ppm. The high-Ti volcanics have higher concentrations of FeO^T (~17 wt.% to 15 wt.%) compared to the low-Ti volcanics (~14 wt.% to 12 wt.%). The high-Ti volcanics are more evolved in terms of their FeO^T/MgO ratios, whereas in terms of SiO_2 , the low-Ti volcanics are more evolved. In the (Zr + Y) vs ($\text{TiO}_2 \times 100$) vs Cr plot¹³, the low-Ti suites are classified as magnesian tholeiites, whereas the high-Ti suites are normal tholeiites. In the CaO/TiO_2 and $\text{Al}_2\text{O}_3/\text{TiO}_2$ versus TiO_2 plots (Figure 2), the low-Ti suites of all the Khairagarh volcanics have higher CaO/TiO_2 and $\text{Al}_2\text{O}_3/\text{TiO}_2$ ratios and spread around the primitive (i.e. modal pyrolite) compositions, whereas the high-Ti suites have lower CaO/TiO_2 and $\text{Al}_2\text{O}_3/\text{TiO}_2$ ratios, and plot away from the primitive composition. Assuming a simple pyrolite source, this diagram indicates that the low-Ti and high-Ti volcanics represent higher and lower degrees of partial melting, respectively⁵.

The low-Ti volcanics show LREE enriched patterns (Ce/Sm_N : 2.43 and 2.85), whereas the high-Ti volcanics show moderately enriched LREE patterns (Ce/Sm_N : 1.55

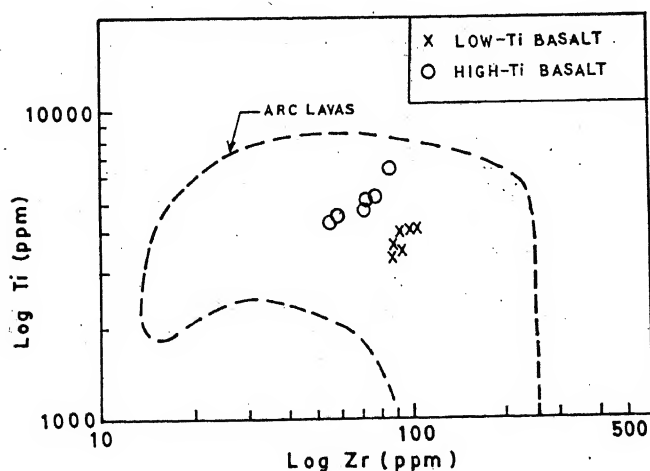

Figure 1. TiO_2 vs Zr plot showing two distinct trends in Khairagarh Volcanics, Sitagota Syncline. Also shown is the volcanic-arc lava field of Pearce (1982).

Yb	1.6	2.4
Lu	0.2	0.4

to 1.85). The HREE patterns of the low-Ti volcanics are almost flat (Gd/Yb_N : 1.29 to 1.67), whereas the high-Ti volcanics have flat to moderately fractionated HREE patterns (Gd/Yb_N : 1 to 2.01). The contrasting REE patterns together with subtle major and minor element differences rule out the possibility of relating the high-Ti and low-Ti volcanics by any conceivable fractionation processes¹⁴. The primitive nature of these samples rule out the possibility of crustal contamination to relate them¹⁴⁻¹⁶.

Another distinct feature is the presence of pronounced negative Eu anomalies in the low-Ti volcanics, indicating plagioclase fractionation. In island-arc related suites, early plagioclase removal takes place under low P_{H_2O} conditions^{17,18}. This is also corroborated by the behaviour of V, which increases with fractionation in the low-Ti volcanics, whereas lack of plagioclase removal in the high-Ti volcanics (i.e. no Eu anomaly) indicates relatively high P_{H_2O} condition, however, not high

Figure 2. TiO₂ vs CaO/TiO₂ and Al₂O₃/TiO₂ plots (after Sun and Nesbitt⁶) for high-Ti and low-Ti volcanics of Khairagarh Group. Fields of Mid-oceanic Ridge Basalt (MORB), Spinifex-textured periodotitic komatiites (STPK) and low-Ti arc basalts or ophiolites⁶. Fields of low-Ti volcanics (LS, LD and LN respectively) and high-Ti volcanics (HS, HD and HN respectively) are for Khairagarh volcanics^{7,9,10}.

Fig. 3

Figure 3. Chondrite normalized REE patterns of representative samples of low-Ti and high-Ti volcanics, Khairagarh Group.

enough to produce calc-alkaline volcanics^{17,18}. High P_{H_2O} conditions in the generation of high-Ti suite is corroborated by the falling concentrations of V with fractionation. V versus Yb plot¹⁹ also indicates relatively

higher f_{O_2} conditions in the high-Ti suite, compared to the low-Ti volcanics; between QFM and higher than QFM + 1.

The mantle source of the low-Ti volcanics was LREE enriched (i.e. E-MORB and/or higher subduction flux²⁰) compared to the high-Ti volcanics. Higher proportions of garnet in the mantle residue of the low-Ti volcanics retained Ti, HREE and Sc compared to the high-Ti volcanics. Therefore, the subtle major and minor element differences between the arc-related high-Ti and low-Ti volcanics (Figures 1–3) are neither related to elemental mobility, nor can they be explained by clinopyroxene and plagioclase fractionation²¹, but are due to different degrees of partial melting of a heterogeneous mantle source (with respect to garnet) under different P_{H_2O} , f_{O_2} and subduction fluxing conditions.

The enriched MORB source of the low-Ti volcanics implies early stages of back-arc spreading, as in the Izu-Marianas arc or interarc rifting²⁰ and provides a simple explanation for the paradoxical presence of interlayered sedimentary formations of the Khairagarh Group⁷. Similarly, the presence of only tholeiitic lavas in the Khairagarh volcanics indicates the subduction of a relatively young and thin (< 20 km) oceanic plate with relatively high (> 7 cm/yr) convergence rates²².

Unusual aspects of pressure-induced phase transitions in CuGeO_3

University of Hawaii, Hawaii Institute of Geophysics and Planetology, Honolulu, HI 96822, USA

*Lucent Technologies, Bell Labs Innovations, Murray Hill, NJ 07974, USA

High pressure Raman and optical studies on the spin-Peierls compound CuGeO_3 have revealed three novel pressure-induced phase transitions in the 7–8 GPa range. One of these occurring only under hydrostatic conditions, is believed to be a ferroelastic-ferroelectric phase. The other two high pressure phases are brilliant blue and green, respectively. Of these, the blue-phase is quenchable, while the green-phase reverts to the blue. From crystal chemistry, Raman spectral features and metastability considerations, it is suggested that the blue and the green phases have the pyroxene type chain structure similar to enstatite polymorphs, and non-hydrostatic pressure is essential for the formation of pyroxene type chain structures.

COPPER metagermanate (CuGeO_3) is a very interesting material, for it is the first inorganic system that exhibits the so-called spin-Peierls transition¹, when cooled below 14 K at ambient pressure. It is a very soft layer-type light blue material (like mica), crystallizing in the orthorhombic space² group Pbmm (C_{2h}^{52}). The backbone of the structure consists of chains (parallel to the c -axis of the crystal) of corner shared GeO_4 tetrahedra linked by edge-sharing CuO_6 octahedral chain co-parallel to the GeO_4 chain², as shown in Figure 1 on the left. The structure is related to the pyroxene family minerals, viz. enstatite, but differs from it in having a unique arrangement of GeO_4 tetrahedra called 'einer' chain, stabilized

Figure 1. The tetrahedral GeO_4 corner sharing extended 'einer' chain with the CuO_6 edge sharing octahedral chain, the backbone of the CuGeO_3 structure. On the right is a pyroxene type extended 'zweier' chain. The chains run parallel to the c -axis of the crystal. Note that all the tetrahedra are on the same side in 'einer' chain whereas in the pyroxene type chain they alternate between the two sides of the chain.

by the tendency of the copper to have Jahn–Teller distorted CuO_6 octahedra. In the 'einer' chain, all of the tetrahedra units lie on the same side of the chain, while in a pyroxene chain they lie on either side (see Figure 1 right side).

From the point of view of high pressure behaviour also, CuGeO_3 is turning out to be very interesting. Our previous high pressure Raman and optical studies on the system³ have revealed the occurrence of a rather unusual type of reversible phase transition near 7 GPa, when 4:1 methanol/ethanol mixture was used. Further extensive studies of the high pressure behaviour of CuGeO_3 carried out recently using Raman spectroscopy and optical microscopy, with a variety of pressure media and with

single crystal and powder samples have yielded a wealth of details. The high pressure behaviour of CuGeO_3 is spectacular and quite complex. We will illustrate some novel aspects of the pressure-induced transitions and discuss them briefly here. A detailed account will be published elsewhere.

Three distinct high pressure phases are encountered in the 7–9 GPa region, when the normal orthorhombic (Phase I) Pbmm (D_{2h}^3) phase of CuGeO_3 (Pmma in the standard notation) is compressed. Surprisingly, the type of phase obtained depends on the hydrostaticity of the pressure medium near 8 GPa. This is shown diagrammatically in Figure 2. Thus when methanol/ethanol mixture, pure methanol or helium is used, the sample abruptly contracts by about 15% in the b -direction of the crystal, near 7 GPa. The resultant high pressure phase which we label as Phase II is pale green and has a different Raman spectrum. On pressure release, the reverse transition takes place near 5.6 GPa. This phase (I to II) transition was first observed in methanol/ethanol mixture earlier, and its amorphization above 15 GPa was documented in the earlier publication by Jayaraman *et al.*³ In the present study, we have observed this very same transition with helium which is a perfect hydrostatic medium up to 11.8 GPa at room temperature⁴, and also in pure methanol which freezes just a little above 7 GPa. The photomicrographs reproduced in Figure 3 show a single crystal sample of CuGeO_3 at different pressures in helium gas as pressure medium in the diamond cell. Figure 3c is the high pressure phase (Phase II). The contraction in the b -axis direction is striking. In Figure 4, the Raman spectrum of CuGeO_3 at 1 bar and at 7.9 GPa in helium is presented.

When argon is used as a pressure medium, the original phase starts to turn blue (designated Phase III) near 7.5 GPa. While this transition is progressing, another phase transition intrudes and the colour of the sample changes to green (designated Phase IV). This transition starts as green stripes traversing the crystal, and then covers the entire sample with increasing pressure. The change in the colour is accompanied by changes in the Raman spectral features. The green phase is stable up to 15 GPa, as judged from its Raman spectral features. When pressure is released, the green-phase transforms to the blue phase near 5 GPa and the latter can be quenched to ambient pressure. The quenched blue phase can be reversed to the original orthorhombic phase, only by heating to 600°C. The blue phase on repressurization transforms to the green phase near 8 GPa and the transformation can be recycled back and forth, irrespective of the pressure medium used. Further, there are no striking changes in the sample dimension accompanying the phase III \rightleftharpoons IV transitions, and the single crystal nature is preserved. In Figure 5, colour photomicrographs of Phase I at two pressures and Phase III and IV at 4 GPa (pressure release cycle) and 11 GPa respectively are

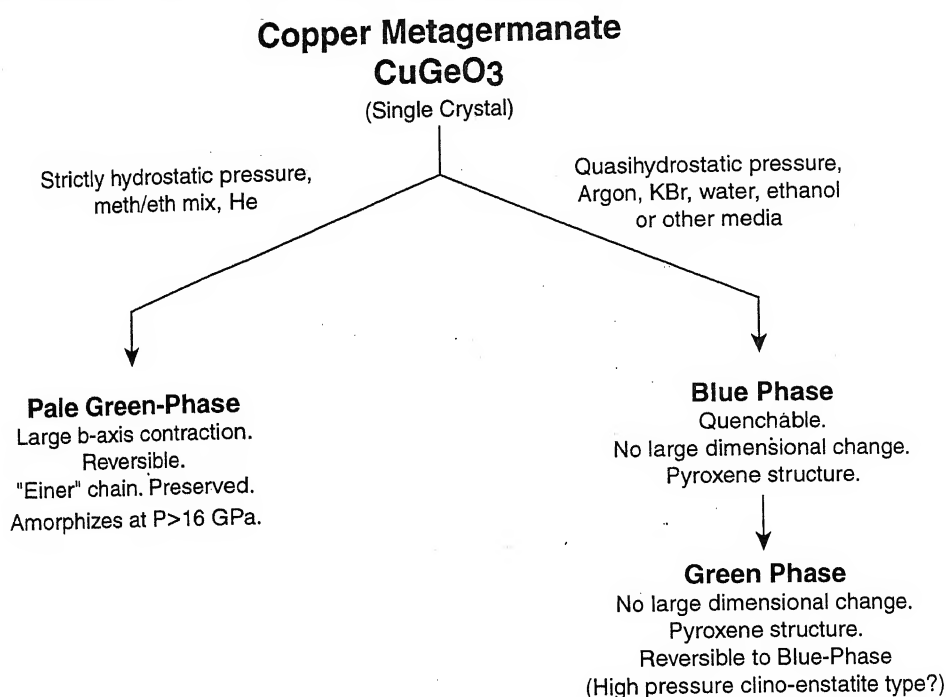

Figure 2. Diagrammatic representation showing the forking of the pressure-induced phase transitions in CuGeO₃, depending on the nature of stress.

presented. The pressure medium was argon. The Raman spectra of the green phase (IV) recorded near 5.6 GPa, and of the blue phase (III) near 4 GPa (both on the pressure release cycle) are shown in Figure 6.

With all other pressure media, the results obtained are similar to those described in the case of argon since they freeze before 7 GPa. Argon freezes at 1.2 GPa at room temperature. Potassium bromide (KBr) is a soft solid and therefore, behaves as a quasihydrostatic medium.

The results presented raise two main questions: (1) what are the structures of the three high pressure phases and (2) why does the hydrostaticity of the pressure medium have such a strong influence on the nature of the phase transition? Obviously a definite answer to the first question must come from high pressure X-ray diffraction studies on the high pressure phases, preferably single crystal diffraction. An earlier energy dispersive X-ray diffraction study⁵ on CuGeO₃ powder up to 20 GPa reported a phase transition near 7 GPa. For the high pressure phase, a monoclinic cell of $P2_1/m$ symmetry has been proposed. Quite recently, Haines and Adams⁶ have commented that the phase transition reported by us on single crystal CuGeO₃ (ref. 3) must be the same as the orthorhombic to the monoclinic phase mentioned, and not due to intercalation, as we had suggested. Our experience with CuGeO₃ powder is that the Phase I to II transition does not occur unless pressurization is carried out in a hydrostatic medium. From our new findings presented in this paper, it appears to us that the phase transition reported in the X-ray study is most

likely to be from the normal orthorhombic to the green phase.

We will now discuss some possible structures for the blue and the green phases of CuGeO₃, in the light of the known high pressure crystal chemistry of silicate pyroxenes^{7,8}, and the structural features of other metagermanates⁹. In silicate pyroxenes, the SiO₄ tetrahedra form infinite chains by corner sharing along the *c*-axis of the crystal, and the chains are linked by cation polyhedra to form the structure. The tetrahedra lie on either side of the chain (see Figure 1) connected by bridging oxygens and is called a 'zweier' chain, because the periodicity along the *c*-axis is twice the distance of the bridging oxygens. The most important difference between the pyroxene and CuGeO₃ is the so-called 'einer' chain feature, which is unique to this compound². The stability of this chain is believed to be very low because of the strong repulsion of the highly-charged Ge⁴⁺ ions¹⁰. It is the energy gain resulting from the Jahn-Teller distortion of Cu that stabilizes the structure. The pyroxene type 'zweier' chain appears more natural for CuGeO₃. In fact MgGeO₃ has the usual pyroxene type GeO₄ chain and is known to crystallize in the ortho-enstatite (Pbca) and clino-enstatite (C2/c) structure⁹. Thus, we can expect CuGeO₃ to transform from the 'einer' chain type to the pyroxene type of structure at high pressure.

For the blue phase, we suggest the ortho (Pbca) or the low clino-enstatite structure (C2/c), based on crystal chemistry, Raman spectral feature and quenchability. Thus, (i) the magnesium compound MgGeO₃ under

Figure 3 a–c. Photomicrographs of CuGeO_3 single crystal in the diamond cell at three different pressures, with helium as pressure medium (a) 0.5 GPa (b) 5.2 GPa and (c) 8 GPa. The *b* and *c*-axis of the original orthorhombic crystal is marked. Note the large contraction in the *b*-direction in (c). Helium freezes at 11.8 GPa at room temperature and is a gas until then.

ambient conditions crystallizes in these structures⁹, (ii) the observed splitting of the high frequency Raman peak (see Figure 5) representing the symmetric stretch is in accord with the splitting of this mode in both the low-clino and ortho-enstatite¹¹, (iii) finally, the quenchability shows that the pyroxene chain is established in the blue-phase: A change from orthorhombic (Pbmm) CuGeO_3 to pyroxene-type structure must involve a 180° flipping of alternate GeO_4 tetrahedra, to convert the 'einer' chain to 'zweier' type chain and this transition involves breaking of bonds and flipping of the CuO_6 octahedra as well. Once this happens under high pressure, the reverse transition would be kinetically impeded. The observed quenchability of the blue phase and its reversion, only when heated to 600°C is consistent with the above expectation.

Our optical observations in polarized light indicate that the single crystal nature is preserved in the blue phase. Hence, it should be possible to carry out single crystal X-ray diffraction on quenched blue phase and the structural prediction verified. In this phase, the spin-Peierls transition should be absent because of the change in the Cu^{2+} array due to conversion to the 'zweier' type chain.

Once the essential ingredient for the pyroxene structure is established, namely the 'zweier' chain, the behavior of MgSiO_3 under pressure could be used as a guide. It has been shown that both clino-enstatite (MgSiO_3)¹² and ferrosilite (FeSiO_3)¹³ transform under high pressure to a high pressure $C2/c$ phase near 7 GPa and 1.75 GPa, respectively. This phase is denser by about 3% compared to the original phase¹³. The transitions in both

Figure 4. Raman spectrum of single crystal sample of orthorhombic CuGeO_3 at ambient pressure (bottom) and 7.9 GPa, after the phase transition to Phase II. Pressure medium was helium gas. The spectrum is identical to that obtained with methanol/ethanol mixture, as medium.

MgSiO_3 and FeSiO_3 are reversible. The low to high-pressure clino-enstatite transition involves a change from two symmetrically-distinct tetrahedral chains rotated in opposite directions to one symmetrically-distinct tetrahedral chain. We suggest that a similar phase transition occurs in the green phase of CuGeO_3 . Its reversibility and the Raman spectral feature support this interpretation.

The pale green phase-phase II transition occurs only when the pressure medium is *strictly hydrostatic* and not otherwise, and is a very unusual behaviour. For this phase transition, intercalation by the pressure medium (alcohol) was suggested³. However, the occurrence of the very same transition with helium gas also, throws some doubt on the intercalation idea. The presence of a single strong Raman peak in the ν_s (Ge-O-Ge) and ν_s (Ge-O⁻) mode region (see Figure 1) is a strong indication that the 'einer' chain feature is preserved in this phase.

All the evidence we have accumulated so far point to the fact that this Phase I to II transition is abrupt and cannot involve any bond breaking. A sliding or partial rotation of the chain must occur in the structure, to cause the crystal to contract abruptly in the b -axis direction. If the crystal is constrained by a solid pressure medium, this contraction will be impeded and the transition suppressed. When this happens, the competing phase transition to the pyroxene structure takes over, and the 'einer' chain turns into pyroxene-type 'zweier' chain, to minimize the free energy of the compressed system, triggering the blue and then the green phase sequence. Therefore, the freedom for the b -axis to contract or expand is a stringent requirement for I to II phase transition to occur. This would explain the extreme sensitivity of the transition to the hydrostaticity of the medium. These aspects suggest that phase II might be a strongly-coupled ferroelastic system. Usually a ferroelastic transition is coupled to a ferroelectric transition also. One of the sure indications for the latter would be the presence of ferroelectric domains. However, we do not observe any domains in the high pressure phase II when examined in crossed polarization under the microscope. But we believe that the observed jumping of the crystal inside the diamond cell at the transition when helium is used as a pressure medium is significant, and may be connected with the development of electric charge in the crystal due to the sudden compression in the b -axis direction of the crystal. That a ferroelectric crystal when suddenly compressed can get charged is well known. Therefore, it may be that this high pressure phase II of CuGeO_3 is ferroelectric-ferroelastic. Such a coupled situation is known, as is exemplified in the β' -phase of $\text{Tb}_2(\text{MoO}_4)_3$ (ref. 14).

The high pressure behaviour of CuGeO_3 has many interesting facets. The elucidation of the structural features of the high pressure phases by single crystal X-ray diffractions is an inviting challenge to the crystallographer. Once the symmetry and space groups are determined, the interpretation of the vibrational spectra could lead to further insights into the high pressure behaviour. The anomalous b -axis compression carries the key to understand pressure-induced instabilities, just as it is significantly connected to the spin-Peierls instability at low temperatures. The large b -axis contraction at the I to II transition and the extreme sensitivity of the latter to the nature of applied stress suggests a strongly-coupled ferroelastic phase for phase II, with the possibility of ferroelectric behaviour in addition. Application of pressure is a route to prepare a new polymorph of CuGeO_3 , namely, the blue phase at ambient pressure. The properties of this would be of interest. The colours of the phases are rooted in the electronic structure of Cu^{2+} , a $3d^9$ Jahn-Teller ion. A deeper understanding of the absorption features could connect, Jahn-Teller distortion, structure and absorption. Finally, the possibility of

Figure 5. Colour photomicrographs of single crystal CuGeO_3 at four different pressures. Pressure medium argon (a) 1 GPa (b) 5 GPa (c) 4 GPa and (d) 11 GPa. (b) and (c) taken on the pressure release cycle. The b and c-axis of the original orthorhombic Pbnm phase marked.

Figure 6. The Raman spectrum of CuGeO_3 single crystal sample in the blue-phase at 4.1 GPa, green-phase at 5.6 GPa, obtained on the pressure release cycle with 514.5 nm excitation. Note the splitting of the high frequency peaks (symmetric stretch).

phase transitions to garnet, ilmenite and perovskite structure exists, in analogy with the behaviour of other germanates and silicates.

Synthesis and anticancer activity of new derivatives of podophyllotoxin

Wang Yan-guang, Pan Jian-lin and
Chen Yao-Zu*

Department of Chemistry, Zhejiang University, Hangzhou 310 027, P. R. China

A series of analogues of etoposide (VP-16,1), the C-4 alkylamino-substituted 4'-dimethyl-epipodophyllotoxins (4a-g), have been synthesized and studied for their activity to inhibit L1210 and KB cells *in vitro*. Compounds 4a, 4b, 4c and 4f are as potent or more potent than VP-16 in their inhibition of both L1210 and KB cells.

THE clinical efficacy and intriguing mechanism of podophyllotoxin-derived glucoside, etoposide (VP-16, 1), has greatly stimulated interest in the synthesis of new active analogues of podophyllotoxin¹⁻⁶. The approach to modify 1 based on replacement of the glucose moiety with an amino sugar has led to some highly active analogues³, suggesting that β -anomeric configuration was indispensable for the antitumour activity and that the amino substituent of the sugar moiety was important for increasing the activity. Changes in the 4 β -glycosyl group are also of interest for simplified structure which might retain the activity of 1 and its amino glucoside analogues, and be accessible to practical industrialization. In the previous papers^{4,7,8}, we reported the synthesis of an amino nitroxyl spin-labeled analogue of 1, GP-7(2), which exhibited superior pharmacological properties to 1. A series of 4 β -alkylamino and arylamino

derivatives of 4'-demethylepipodophyllotoxin, such as 3a-c, have also demonstrated by the strong antitumour activity that considerable simplification in the sugar structure might be permitted so long as the amino group was retained^{5,6,9}. These findings prompted us to change the C-4 glucose moiety in VP-16 to a configurationally similar amino-acid ester, and to synthesize seven new derivatives of podophyllotoxin (4a-g).

4 β alkylamino derivatives of 4'-demethylepipodophyllotoxin (4a-g) were synthesized by direct nucleophilic substitution (SN1) of appropriate L-amino-acid ester (7a-g) with 4 β -bromo-4'-demethyl-4-deoxypodophyllotoxin (6) resulting from podophyllotoxin (5). The bulky C-1 α pentant aromatic ring dictates the substitution to be stereoselective in yielding the C-4 β alkylamino isomers as the major products. In some cases, the C-4 α isomers were also observed. The assignment of the configuration at C-4 for compounds 4a-g was based on the difference of $J_{3,4}$ coupling constants. The C-4 β -substituted compounds 4a-g have a $J_{3,4} \approx 4.0$ Hz as seen in 1 and 3 (refs. 5, 6), due to a *cis* relationship between H-3 and H-4. The C-4 α substituted derivatives, however, have a $J_{3,4} \geq 10.0$ Hz as H-3 is *trans* to H-4 (ref. 6).

We have tested the inhibitory activities of compounds 4a-g against leukaemia L1210 and KB cells *in vitro*. ID₅₀ values of compounds 1 and 4a-g are 0.40, 0.28, 0.42, 0.38, 0.70, 1.60, 0.42 and 1.25 μ M for L1210 cells, and 0.22, 0.20, 0.10, 0.18, 0.56, 0.84, 0.28 and 1.00 μ M for KB cells, respectively. Therefore, compounds 4a, 4b, 4c and 4f are as potent or more potent than VP-16 in their inhibition of both L1210 and KB cells. These results demonstrate the possibility of considerable simplification in the sugar structure of 1 and suggest further elaboration of the 4 β -amino substituent to optimize the structure of this class of anticancer compounds. Further study for anticancer activity of synthesized compounds is in progress.

All melting points were taken on Yanaco melting point apparatus and uncorrected. IR spectra were obtained on a Nicolet-5DX spectrophotometer, and ¹HNMR spectra were obtained by using either a Bruker AM-400 or JMS-FX-90Q NMR spectrometer. All chemical shifts are reported in ppm from TMS. Elemental analysis were taken on a YANACO-CHN-CODER MT-3 instrument. MS analysis were determined on a VG-7070E-HF instrument at 70 eV.

A solution containing 4 β -bromo-4'-demethyl-4-deoxypodophyllotoxin (6) (ref. 1) (1.5 mmol), anhydrous barium carbonate (2.0 mmol), and the appropriate L-amino-acid ester (7a-g) (2.0 mmol) in 20 ml of dry 1,2-dichloroethane under nitrogen was stirred overnight at room temperature. The reaction mixture was filtered, diluted with ethyl acetate, washed with water, dried, and purified via column chromatography (50 g of silica gel with dichloromethane-acetone 8:1 as eluant). Yields ranged from 18 to 47%.

(s, 6H, 3', 5'- OCH_3), 3.30 (s, 2H, NHCH_2), 3.24 (dd, $J = 5.0, 14.0$ Hz, 1H, H-2), 2.75 (m, 1H, H-3), 1.92 (s, 1H, NH), 1.24 (t, $J = 7.2$ Hz, 3H, CH_2CH_3). Anal. calculated for $\text{C}_{25}\text{H}_{27}\text{NO}_9$, C 61.85, H 5.61, N 2.89; found C 61.83, H 5.65, N 2.88.

Compound 4b: m.p. 227–228°C; MS m/z $[M]^+$ 471; IR (KBr) 3500 (OH), 3420 (NH), 1760 (lactone), 1734

(ester), 1610, 1511 and 1485 (aromatic C=C) cm^{-1} ; ^1H NMR (CDCl_3), δ 7.00 (s, 1H, H-5) 6.39 (s, 1H, H-8), 6.21 (s, 2H, H-2', 6'), 5.91 (m, 2H, OCH_2O), 5.10 (s, 1H, 4'-OH), 4.49 (d, $J = 5.0$ Hz, 1H, H-1), 4.28 (m, 2H, H-11), 3.89 (d, $J = 4.0$ Hz, 1H, H-4), 3.72 (s, 3H, CO_2CH_3), 3.65 (s, 6H, 3', 5'- OCH_3), 3.37 (s, 2H, NHCH_2), 3.29 (dd, $J = 5.0$ Hz, 14.0 Hz, 1H, H-2), 2.99 (m, 1H, H-3), 2.20 (s, 1H, NH). Anal. calculated for $\text{C}_{24}\text{H}_{25}\text{NO}_9$, C 61.14, H 5.34, N 2.97; found C 61.17, H 5.31, N 3.01.

Compound 4c: m.p. 214–215°C; MS m/z $[\text{M}]^+$ 485; IR (KBr) 3435 (OH, NH), 1772 (lactone), 1742 (ester), 1612, 1515 and 1483 (aromatic C=C) cm^{-1} ; ^1H NMR (CDCl_3), δ 7.02 (s, 1H, H-5) 6.38 (s, 1H, H-8), 6.22 (s, 2H, H-2', 6'), 5.85 (s, 2H, OCH_2O), 5.12 (s, 1H, 4'-OH), 4.42 (d, $J = 4.8$ Hz, 1H, H-1), 4.20–4.00 (m, 2H, H-11), 3.92 (d, $J = 4.0$ Hz, 1H, H-4), 3.78 (s, 3H, CO_2CH_3), 3.70 (s, 6H, 3', 5'- OCH_3), 3.65 (q, $J = 6.8$ Hz, 1H, NHCH), 3.13 (m, 1H, H-2), 2.80 (m, 1H, H-3), 2.06 (s, 1H, NH), 1.15 (d, $J = 6.8$ Hz, 3H, CHCH_3). Anal. calculated for $\text{C}_{25}\text{H}_{27}\text{NO}_9$, C 61.85, H 5.61, N 2.89; found C 61.90, H 5.62, N 2.84.

Compound 4d: m.p. 178–179°C; MS m/z $[\text{M}]^+$ 513; IR (KBr) 3470 (OH, NH), 1770 (lactone), 1736 (ester), 1610, 1508 and 1482 (aromatic C=C) cm^{-1} ; ^1H NMR (CDCl_3), δ 7.00 (s, 1H, H-5) 6.39 (s, 1H, H-8), 6.23 (s, 2H, H-2', 6'), 5.83 (ABq, $J = 1.0, 4.5$ Hz, 2H, OCH_2O), 5.00 (s, 1H, OH), 4.38–4.22 (m, 3H, H-1 and H-11), 3.90 (d, $J = 4.0$ Hz, 1H, H-4), 3.82 (s, 3H, CO_2CH_3), 3.77 (s, 6H, 3', 5'- OCH_3), 3.69 (d, $J = 7.4$ Hz, 1H, NHCH), 3.16 (dd, $J = 5.0, 12.0$ Hz, 1H, H-2), 2.80 (m, 1H, H-3), 2.30 (m, 1H, CHMe_2), 2.21 (s, 1H, NH), 1.10 (d, $J = 7.4$ Hz, 6H, $\text{CH}(\text{CH}_3)_2$). Anal. calculated for $\text{C}_{27}\text{H}_{31}\text{NO}_9$, C 63.15, H 6.08, N 2.73; found C 63.10, H 6.05, N 2.72.

Compound 4e: m.p. 170–172°C; MS m/z $[\text{M}]^+$ 561; IR (KBr) 3500 (OH), 3380 (NH), 1776 (lactone), 1726 (ester), 1612, 1516 and 1485 (aromatic C=C) cm^{-1} ; ^1H NMR ($\text{DMSO}-d_6$), δ 7.35 (m, 5H, C_6H_5), 6.89 (s, 1H, H-5), 6.55 (s, 1H, H-8), 6.34 (s, 2H, H-2', 6'), 5.90 (s, 2H, OCH_2O), 5.41 (s, 1H, OH), 4.44 (d, $J = 8$ Hz, 1H, H-1), 4.38–4.09 (m, 3H, H-11, NH), 3.90 (d, $J = 4.2$ Hz, 1H, H-4), 3.70 (s, 3H, CO_2CH_3), 3.68 (s, 6H, 3', 5'- OCH_3), 3.64 (t, $J = 7.0$ Hz, 1H, NHCH), 3.32 (d, $J = 7.0$ Hz, 2H, CH_2Ph), 3.10 (m, 2H, H-2, 3). Anal. calculated for $\text{C}_{31}\text{H}_{31}\text{NO}_9$, C 66.30, H 5.56, N 2.49; found C 66.38, H 5.58, N 2.47.

Compound 4f: m.p. 197–198°C; MS m/z $[\text{M}]^+$ 577; IR (KBr) 3450 (OH, NH), 1775 (lactone), 1734 (ester), 1610, 1505 and 1480 (aromatic C=C) cm^{-1} ; ^1H NMR ($\text{DMSO}-d_6$, D_2O exchange), δ 6.90 and 6.70 (d, $J = 8.3$ Hz, 4H, C_6H_4), 6.82 (s, 1H, H-5), 6.51 (s, 1H, H-8),

6.26 (s, 2H, H-2', 6'), 5.95 (s, 2H, OCH_2O), 4.48 (d, $J = 5.0$ Hz, 1H, H-1), 4.37 (m, 2H, H-11), 3.95 (s, 3H, CO_2CH_3), 3.83 (d, $J = 4.1$ Hz, 1H, H-4), 3.75 (s, 6H, 3', 5'- OCH_3), 3.67 (t, $J = 7.0$ Hz, 1H, NHCH), 3.30 (d, $J = 7.0$ Hz, 2H, CH_2Ph), 3.18–3.11 (m, 2H, H-2, 3). Anal. calculated for $\text{C}_{31}\text{H}_{31}\text{NO}_{10}$, C 64.46, H 5.41, N 2.43; found C 64.31, H 5.39, N 2.44.

Compound 4g: m.p. 130–131°C; MS m/z $[\text{M}]^+$ 541; IR (KBr) 3443 (OH, NH), 1772 (lactone), 1733 (ester), 1605, 1503 and 1485 (aromatic C=C) cm^{-1} ; ^1H NMR (CDCl_3), δ 6.94 (s, 1H, H-5), 6.46 (s, 1H, H-8), 6.19 (s, 2H, H-2', 6'), 5.91 (m, 2H, OCH_2O), 5.32 (s, 1H, OH), 4.47 (d, $J = 5.0$ Hz, 1H, H-1), 4.28–4.00 (m, 4H, H-11, CO_2CH_2), 3.80 (d, $J = 4.2$ Hz, 1H, H-4), 3.74 (s, 6H, 3', 5'- OCH_3), 3.66 (t, $J = 7.0$ Hz, 1H, NHCH), 3.30 (m, 1H, H-2), 2.94 (m, 1H, H-3), 2.18 (s, 1H, NH), 1.85 (m, 3H, CH_2CHMe_2), 1.28 (t, $J = 7.2$ Hz, 3H, CH_2CH_3), 0.97 (d, $J = 6.6$ Hz, 6H, $\text{CH}(\text{CH}_3)_2$). Anal. calculated for $\text{C}_{29}\text{H}_{35}\text{NO}_9$, C 64.31, H 6.51, N 2.59; found C 64.21, H 6.50, N 2.62.

Drugs were dissolved in Me_2SO at a concentration of 20 mM as the stock solution and diluted before use with H_2O to the desired concentration of each drug. The cytotoxicity was determined *in vitro* using L1210 and KB cells grown in RPMI No. 1640 medium supplemented with fetal calf serum according to the published procedure^{9,10}.

Biofilms were grown in laboratory conditions by exposing a range of alloys such as stainless alloys (grade-2 titanium, 6XN, 316L, 904L, Seacure, C276, platinum), aluminium 2S, aluminium 6061, chromium, nickel, molybdenum, copper and cupro-nickel (90:10) to natural pond water. On the basis of photo-electrochemical studies, the oxide films on the above materials were classified as n or p type semiconductors. Alloys having an overlayer of n-type semiconducting oxide film only exhibited a substantial positive shift of corrosion potential. Capacitance measurements were employed to analyse the changes in donor concentration within the oxide film during the ennoblement process. Bacterial and chemical constituents of the biofilm were also analysed. Results of the study strongly suggest that the mechanism of ennoblement is linked to the bacterial removal of excess 'anions' and 'cations' from the oxide film.

BIOFILMS from fresh as well as sea waters usually shift the open circuit potential of stainless steels by several hundred millivolts¹⁻⁵. Johnsen and Bardal⁶ suggested that this process of ennoblement is linked to organo-metallic catalysis of the oxygen reduction reaction. Alternatively, the groups of Dexter hypothesized that the ennoblement is caused by a decrease in pH^{2,7,8} at the metal surface by respiring organisms and by the production of peroxide³. Maruthamuthu *et al.*⁴ proposed that the ennoblement is not an effect of low pH but rather linked to neutral pH conditions. Eashwar *et al.*⁵ explained that the ennoblement was caused by anodic passivation following neutral pH. Eashwar and Maruthamuthu⁹ have also pointed out that siderophores produced by bacteria could be important to ennoblement.

Most recently, Maruthamuthu *et al.*¹⁰ proposed an adsorbed inhibitor theory which emphasized an importance for oxide film in the process of ennoblement. In the

present investigation, the contributions of oxide film and bacterial metabolism are examined.

The tests were conducted on grade-2 titanium, stainless steels (316L, 904L, Seacure), super alloys (C-276, 6XN), platinum, aluminium 2S, aluminium 6061, chromium, nickel, molybdenum, copper and cupro-nickel (90:10). The samples were pickled in appropriate acids¹¹, polished with 400 grade emery, degreased in acetone and rinsed in distilled water prior to all tests. The compositions of the different alloys used are given in Table 1.

For potential measurements, the various alloys were exposed to freshly-sampled pond water in laboratory conditions. Open circuit potentials (OCP) were measured with respect to a saturated calomel electrode (SCE) using a 4 digit high impedance multivoltmeter (HIL 2605). Coupons of 5 cm × 2 cm size were used for potential measurements.

The impact of dissolved oxygen concentration (DO) on potential of titanium was also examined by lowering the dissolved oxygen concentration by the addition of sodium sulphite to the filter-sterilized (0.2 micron) water.

For photopotential measurements, two identical electrodes of each metal/alloy were polished to a mirror finish, degreased with trichloroethylene and lacquered to obtain a geometrical area of 1 cm². An all-PVC cell (300 ml capacity) consisting of two compartments, separated by a thin perforated sheet, was so designed that one electrode could always be kept in the dark while the other could be irradiated through a quartz window as and when required. In all the above systems, biofilms were grown on the coupons by renewing the natural pond water every day. Depending upon the direction of the photopotential, the overlaying oxide film was identified as n- or p-type semiconductor.

Capacitance measurements were carried out using a conventional three-electrode electrochemical system with platinum foil as the auxiliary electrode and saturated calomel as the reference electrode using PAR electrochemical impedance system. Two 904L coupons exposed to natural and filtered pond water for 40 days were used as the working electrodes.

The nutrient content of the biofilm was analysed at various time intervals after immersion. The biofilm was scrapped using a uniform edged sterilized knife and collected in 100 ml triple distilled water. This sample was used for estimating dissolved nitrite, nitrate, total phosphorus and inorganic phosphates according to Grasshoff *et al.*¹².

Figure 1 shows the open circuit potential (OCP) for 316L stainless steel, chromium, nickel and molybdenum exposed to pond water. It clearly indicates that the OCP of 316L stainless steel alone increases with time to more positive values.

This paper won the Eureka Forbes 1995 Award at the National Symposium on Frontiers in Applied Environmental Microbiology, Cochin, 11-13 December 1995.

Figure 1. Potentials for 316L SS, nickel, chromium and monel in biotic system.

The OCPs of 6XN, 904L, Seacure and C-276 with time are shown in Figure 2. A large ennoblement is observed for 6XN and the least for C-276.

Table 2 presents the data on the ennoblement range, magnitude of photopotential and semiconducting type of oxide film for various metals/alloys after 32 days of immersion in natural pond water.

The Mott-Schottky ($1/C^2$ vs E) plots for 904L biofilmed electrode and unbiofilmed electrode in pond water are shown in Figure 3. An increase in $1/C^2$ values (i.e., decrease of capacitance) (see ref. 15) is observed on biofilmed specimen as compared to the control specimen. From the capacitance measurement, donor

concentrations (at 1000 Hz) as calculated from the slope of the linear region of the curves, are 5.3371×10^{17} for the biofilmed specimen and 1.5929×10^{18} for the bare specimen.

Figure 4 shows the OCP of titanium in filter sterilized deaerated or aerated pond water (pH 8.6 to 9.2) with time. A decrease in dissolved oxygen shifts the potential of titanium to more negative values whereas in deaerated water there is not much fluctuation in OCP.

Figure 5 shows the adsorbed nutrients value of biofilm on titanium. Total phosphorus and nitrate are high in 10 days old biofilm. Estimated nitrite value is low on all days.

Table 2. Data on ennoblement range, amount of photopotential and nature of oxide film for various alloys

Materials	Ennoblement range (mV)	Photopotential	Nature of oxide film
316L SS	300–400	–40	n-type
Chromium	No ennoblement	+10	p-type
Nickel	No ennoblement	+10 – +15	p-type
Molybdenum	No ennoblement	–	Unstable (bluish black)
904L	275–300	–25	n-type
6XN	330–375	–30	n-type
C-276	200	–10 to 13	n-type
Seacure	250	–20	n-type
Titanium	300	–52	n-type
Platinum	450	–50	n-type
Aluminium 2S	No ennoblement	+2	p-type
Aluminium 6061	No ennoblement	+3	p-type
Copper	No ennoblement	+75	p-type
Cupro-nickel	No ennoblement	+60	p-type

**Figure 2.** Potentials for stainless alloys of C276, 6XN, 904L and seacure in biotic system.

In the present study, the photopotentials have been measured to determine the nature of oxide film on various alloys. The photopotential of a metal oxide can be expressed as

$$V_{ph} = KT/(e \ln (N_A/N_D)), \quad (1)$$

where N_A and N_D are the concentrations of acceptor and donor corresponding to those excessive anions and cations and the stoichiometric composition of oxide film^{13,14}. Alloys can be classified as n-type or p-type semiconductors based on the negative or positive shift in potential due to light.

It is seen from Table 2 that a positive shift (ennoblement) in OCP is observed only for metals/alloys having an n-type semiconducting oxide film. Figure 1

explains that while ss 316 shows an ennoblement, the same is not the case for chromium, nickel and molybdenum. This is because chromium and nickel have p-type semiconducting oxide films and molybdenum has an unstable black oxide film. It has to be explained here that even though chromium is present in stainless steel, FeOOH is in outer layer and Cr_2O_3 is in the inner layer¹⁵. The outer layer therefore acts as an n-type oxide and supports the ennoblement process.

The positive shifts in corrosion potential are large for 6XN, 904L and Seacure but least for C-276 (Figure 2). Results in Table 2 indicate that the semiconducting oxide film on C-276 is an n-type, although the alloy contains high percentage p-type inclusions such as nickel, chromium and molybdenum (Table 1). The high per-

Figure 3. Capacitance vs potential in biotic and abiotic system for 904L at 1000 Hz.

Figure 4. Potential values in various oxygen concentrations.

centage of these inclusions, especially molybdenum¹⁵ might reduce the donor concentration on C-276 alloy and hence be the reason for the least positive shift. But the reason for the high ennoblement range in Delaware waters⁸ and Tuticorin (personal observation) for C-276 needs further exploration. The present observation

Figure 5. Concentrations of various nutrients in biofilm.

Figure 6. Model for ennoblement mechanism.

suggests that the range of positive shifts for various alloys may depend upon the donor concentration (excess cations) of oxide films. Hence, capacitance measurement has been taken for 904L with and without biofilm.

For a semiconducting/electrolyte interface, the net capacitance C is related to the capacitance of the space charge layer C_{SC} and the capacitance of the Helmholtz layer C_H according to

$$1/C = 1/C_{SC} + 1/C_H \quad (2)$$

Normally, the capacitance associated with the Helmholtz region is very large compared to that of space charge region and therefore the total capacitance C will correspond to C_{SC} . The $1/C^2$ vs potential plots were analysed using the expression for the space charge capacitance of a semiconductor in the depletion region

$$1/C^2 = 2/(\epsilon\epsilon_0 e N_D (V - V_{fb} - KT/q)), \quad (3)$$

where ϵ is the dielectric constant of the film, N_D the donor concentration, V the applied electrode potential, V_{fb} the flat band potential and the remaining symbols have their usual meaning. According to the equation, the donor concentration can be calculated from the slope of the linear region. The calculation of donor concentration requires the knowledge of the dielectric constant of the films.

In the present study, increased oxide film thickness¹⁰ and decreased donor concentration were observed in presence of a mature biofilm. The capacitance values were also less the biofilmed sample as compared to the control. This result may be explained in terms of the production of anions by bacterial metabolism which could reduce the donor concentration of the oxide film by neutralization with excess cations. The results also suggest that the organic nutrients can act as a semiconductor and enhance the thickness of the oxide film.

According to Chao *et al.*¹⁶, thin passive films contain many lattice defects and as shown by Sato *et al.*¹⁷ for passive iron, the density of these defects acting as electron donors decreases with increasing film thickness because the film tends to take a more stable structure. The lower N_D values obtained in neutral solutions confirm that the amorphicity of the passive films decreases with increasing film thickness. Increasing thickness of the oxide film and anion production by biofilm are a continuous and permanent process which can strengthen the oxide film and make it more stable. This mechanism is similar to the observations made by Irhzo¹⁸ on stainless steel in presence of molybdenum anions. The molybdenum anions MoO_4^{2-} neutralize the positive donors of oxide film, decrease the conductivity and possibly repel the chloride adsorption to increase the pitting resistance of stainless steels.

Figure 4 explains the positive shift in OCP at high oxygen levels. Viera *et al.*¹⁹ also observed the shift in the noble direction in the case of stainless steel when ozone was present in a cooling water system. The positive shifts in chloride solution were also observed by some authors^{10,20}. These abiotic positive shifts may be explained as the availability of anions (O^- ; Cl^-) may influence the oxide film which may favour the positive shift.

However, Little *et al.*²⁰ have performed oxygen measurements through microprobe to show that the biofilm substratum interface remained virtually oxygen free. Guezennec²¹ clearly showed that an appreciable ennoblement started after 20 days only, when anaerobic bacteria begin to flourish. Further, the sharp influence in corrosion potential was coincident with an increase in the numbers of *Desulphovibrio* and *Desulphatovaculum* species. The potential after a gradual increase up to 50th day, remained unchanged for a further period of 30

days, which was characterized by the domination of these anaerobic species. Recently Eashwar and Maruthamuthu⁹ concluded that anaerobic bacterial activity is to be expected in all biofilms. In the present study also, the ennobled specimens of 316L in the OCP of around +390 were maintained up to 6 months in the freshwater. Hence, it suggests that in presence of biofilm, the oxygen and chloride are not needed for ennoblement.

Generally, the oxide growth may occur by cationic movement outwards from the metal/oxygen interface or by anionic movement inwards²². Hence, the abiotic and biotic shift may be explained by movement of anions/cations of oxide film.

Figure 5 shows that the biofilm contains high amounts of organic phosphate with nitrates and nitrites. Maloney *et al.*²³ have explained the anion exchange mechanism for both gram-positive and negative cells. The bacteria, for maintenance of a physiological carbon : phosphorus ratio (40:1) during the growth of the cell, brings out the too little carbon and too much phosphorus from the cell in the form of glucose-6-phosphate anion (G6P^-) (Figure 6). Bhosle *et al.*²⁴ have recently identified eight major individual sugars like arabinase, fructose, galactose, glucose, mannose, rhamnose, ribose and xylose in micro-fouling material. The proposed mechanism is that the anion of organic phosphate combines with excess cations of n-type oxide film leading to both strengthening of oxide film and a positive shift in the corrosion potential. The 'mixed, biologically produced, organic complex' may act as 'anion', strengthen the 'oxygen starved'²¹ oxide film for long periods of time. Further study is in progress to present more evidence in support of this novel mechanism.

Defective neurulation in frog embryos exposed to dilute sea water

H. V. Ghate, A. D. Padhye and
Surendra Ghaskadbi*†

Post-graduate Research Centre, Department of Zoology, Modern College, Pune 411 005, India

*Division of Animal Sciences, Agharkar Research Institute, Agarkar Road, Pune 411 004, India

Embryos of *Microhyla ornata* were exposed to dilute sea water from early gastrula stage onwards for a period of 48 h. The process of neurulation was studied in control and treated embryos by using optical and scanning electron microscopy. In the treated embryos, the neural folds formed normally in the initial period of exposure and subsequently approached each other. However, they failed to fuse mid-dorsally in the cephalic region. In the posterior half of the embryos, the neural folds fused to form the neural tube. Irrespective of this, the treated embryos continued differentiation of the brain, as was evident from the development of the eyes. Failure of ectodermal cells to cover the neural cells may be related to the dramatic surface modifications induced due to high concentration of cations like Na⁺.

EFFECTS of saline medium on amphibian embryos have been widely studied for various reasons. For example, Ely¹ has studied effects of dilute sea water on embryos and tadpoles of a toad, *Bufo marinus*, and has described the tolerance levels. To find out if acidity of breeding ponds is a limiting factor determining distribution of amphibians in New Jersey, Gosner and Black² have in-

vestigated effects of altered pH and salinity on the embryonic development of several species of frogs. With a view to understanding the ecological relationship of amphibians to brackish water, Ruibal³ has studied effects of salinity on embryos of *Rana pipiens*. Salthe⁴, who was interested in finding out the mechanism of increase in the volume of perivitelline space during early amphibian development, has also reported effects of low pH, various cations and anions on the embryos of *R. pipiens*.

In recent years, Beebee⁵ has studied salt tolerance of the embryos of natterjack toad (*Bufo calamita*) because breeding ponds of these toads are subjected to salt spray and tidal inundation in some coastal areas of Britain. Desiccation of breeding ponds due to irregular rainfall and possibility of tidal inundation of ponds in coastal areas prompted Padhye and Ghate⁶ to investigate salt tolerance of the embryos of *Microhyla ornata*.

While studying the ecology of brackish water population of *R. pipiens* from California, Ruibal³ has made an interesting observation regarding neurulation of the embryos exposed to near-lethal concentration of sea water - it has been mentioned that at salinities above 5‰ the surviving embryos displayed anteriorly open neural groove. Similar effects have latter been photographically documented along with brief histology of defective neural tube⁶.

In this paper we provide additional evidence in the form of histological and scanning electron microscopic (SEM) analyses of defective neurulation in *M. ornata* embryos exposed to dilute sea water. The interesting facts emerging out of this work are: (1) the mechanism of neural tube closure may be different along the anteroposterior axis of the neural tube, (2) exposure to saline medium leads to collapsing of elevating neural folds as well as detachment of nonneural and neural ec-

† For correspondence.

Figures 1–4. 1, T. S. control embryo at 24 h (post gastrulation). Note developing eyes and suckers. Neural tube is completely closed and covered over by ectoderm. Scale bar = 100 μ m. 2, T. S. experimental embryo (30% sea water) of the same age as above. Note open neural tube, nonneural ectoderm detaching from the neural cells. Neural folds have, however, approached midline and partially fused (see also Figure 7 for magnified view). Scale bar = 100 μ m. 3, T. S. control embryo (as in Figure 1) through otic capsule region. Again the neural tube is completely closed and has typical morphology. Notochord and otic capsules are well developed. Scale bar = 100 μ m. 4, T. S. experimental embryo of the same age as above. Note highly abnormal neural tube. The ectoderm is widely separated and neural cells are actually falling away. Notochord and otic vesicles are normal. Suckers are also seen on the ventral side. Scale bar = 100 μ m.

toderm from each other and (3) in spite of defective neurulation, development of eye and otic capsule proceeds normally at least for some time.

Embryos of the frog *M. ornata* were collected from local freshwater ponds, jelly was removed manually using forceps and the embryos in early gastrulation (stage 10 of Gosner⁷) were exposed to different dilutions of sea water according to the methods described earlier⁶. The sea water was collected from an apparently unpolluted site on the west coast and stored in a sealed polypropylene jar at about 10°C until use. It was diluted with distilled water so as to obtain 10%, 20% ... 70% sea water. The sea water used was collected from the west coast during heavy monsoon rains and it had salinity of 24 parts per thousand. The total sodium and potassium con-

centration measured by flame photometry was 7200 mg/l and 250 mg/l, respectively.

Since one of the prominent effects of sea water exposure on embryos was defective neurulation, we carried out histological examination as before⁶. In addition, SEM examination was carried out on whole embryos processed as described by Ghaskadbi⁸.

Sea water at a concentration of 60% and more was found to be rapidly lethal to developing embryos of *M. ornata*. At 60% and 70% concentrations, sea water killed all the exposed embryos within a few hours of exposure. Sea water concentration of 40% and 50% was tolerated by most embryos up to about 48 h. In 30% sea water, the embryos survived up to 72 h while 10% and 20% sea water was tolerated beyond 96 h. The experi-

Figures 5–8. 5, T. S. control embryo at 48 h. Note well-developed typically shaped neural tube, eyes and gut. (To choose the appropriate matching section, we had to include this section which unfortunately has a knife mark.) Scale bar = 100 μ m. 6, T. S. experimental embryo at the same age as above. The neural tissue is abnormally fused in the region between the eyes while it is uncovered by ectoderm dorsally. The ectoderm appears to be completely detached from neural tissue and neural folds are collapsing (see Figure 8, magnified view). Scale bar = 100 μ m. 7 and 8, Slightly magnified views of the sections presented in Figures 2 and 6 respectively. Scale bars = 100 μ m.

ments were terminated at 120 h because the purpose was to see effects on early development.

Prominent effects of sea water on embryonic development were observed between 30 and 50% concentration. The effects observed were: failure of the enlargement of perivitelline space, curling of the body axis, reduced percentage of hatching, slight retardation of development and reduced pigmentation. The severity of these effects increased with the increasing percentage of sea water in the medium.

With respect to neural tube development, all embryos exposed to 30–40% sea water showed open neural tube in the head region. In 30% sea water, the embryos were otherwise well-developed and showed normal movement within the vitelline membrane. Most of these abnormal embryos survived for at least 72 h or more. In 40% sea water, however, the embryos were more stunted and, although they also showed open neural tube, most were dead by 48 h. All histological and SEM work was therefore carried out on embryos that survived exposure to 30% sea water.

In 50% sea water, embryonic development was arrested within a few hours of exposure, at about neurula or tail bud stage. Here again the neurulation was not normal. Beyond 50% the embryonic development was arrested as soon as the embryos were exposed, so the event of neurulation could not be observed.

In control embryos, development was quite rapid and normal in all the embryos. There was no mortality or signs of abnormal development in any. By the end of 48 h most control embryos hatched as tadpoles-with-suckers and attached themselves to the wall of the container. In the next 24 hours, eyes and pigmentation developed and the tadpoles were actively swimming. Different regions of the body could be easily observed in these tadpoles (head, trunk, tail).

Comparison of the transverse sections of control and experimental embryos revealed that, in the embryos exposed to 30% sea water, the neural tube was open dorsally in the head region as well as in the anterior part of the trunk region. In the tail region, however, the neural tube had closed. A section passing through the head re-

Figures 9-12. 9, Dorsal view control neurula. Note complete closure of the neural folds. Scale bar = 100 μm . 10, Dorsal view of the corresponding experimental embryo. The neural folds have approached towards the midline and there is delay in fusion. At this stage there is no evidence of detachment of nonneural and neural ectoderm. Scale bar = 100 μm . 11, Later view of 24 h (post gastrulation) control embryo. Note head, trunk and tail as distinct regions of the embryo. Suckers and external gills are also visible. Scale bar = 500 μm . 12, Lateral view of the corresponding experimental embryo. The neural tissue in the anterior two third part is not covered by the ectoderm and the tail is curved. Scale bar = 500 μm .

gion of the control embryo showed well-differentiated neural tube; the eyes and suckers were becoming evident at 24 h post gastrulation (Figure 1). A comparable section of the experimental embryo showed dorsally open neural tube with collapsing neural folds. Nonneural ectoderm had not closed over and neural cells were exposed (Figure 2). Sections passing through the otic-capsule region also indicated that neurulation was badly affected in the experimental embryos (Figures 3 and 4). Development of otic (ear) capsules and notochord was apparently unaffected.

At 48 h the control embryo showed well developed neural tube, eyes and gut region (Figure 5). In the case of experimental embryos, however, the neural tube was wide open and highly abnormal. The nonneural ectoderm had failed to close mid dorsally and the neural

tissue formed a fused mass in between the developing eyes (Figure 6). Figures 7 and 8 are magnified views of the embryos shown in the Figures 2 and 6. These two figures (Figures 7 and 8) clearly point out the distorted development of the neural tube. Eye development was found to be nearly normal, however.

Scanning electron microscopy further revealed that neurulation was affected early in the development. At a stage when control embryos had completed neurulation (Figure 9), the experimentals were lagging behind and the neural folds were still approaching the midline (Figure 10). In a few hours it was clear that the neural folds of the experimental embryos were abnormal and did not fuse in the mid dorsal line. After about 24 h from the commencement of the experiment, the control embryos had reached miniature tadpole stage with

Figures 13–16. 13, Magnified view of the head region of control embryo from Figure 11. Note head–trunk demarcation, external gills and suckers. 14, Magnified view of the head region of the experimental embryo from Figure 12. The neural tissue appears completely detached from the ectoderm and the neural cells are exposed. Note abnormal head shape and absence of external gills. 15, Dorsal view of the control embryo at 24 h. Note head–trunk demarcation. 16, Dorsal view of the experimental embryo at 24 h. There is no clear-cut demarcation of head and trunk region. Neural tissue is not covered over by ectoderm and there is a wide gap between neural cells and ectoderm. Neural folds appear to have fused at least partially. Scale bar = 100 μ m.

definite head, trunk and tail differentiation (Figure 11). The experimental embryos, however, showed considerably collapsed neural folds in the anterior two-third region of the neural tube. There was also overall incomplete differentiation of the head region while the tail was curved upwards (Figure 12). Slightly magnified views of these two figures are presented as Figures 13 and 14. Collapsed neural folds and protruding neural cells were clearly evident in the experimental embryos (Figure 14).

Dorsal view of the control and experimental embryos is presented in Figures 15 and 16, respectively. A considerable gap was observed between the neural and non-neural ectodermal cells of the experimental embryo. Nonneural ectoderm had apparently detached completely from the neural cells (Figure 16), a fact which was also evident from histological analysis (see Figures 6 and 8).

SEM examination of the surface epithelial cells of the control and experimental embryos revealed some striking changes caused by sea water exposure. The surface

of control embryo (trunk region) showed typical epithelial cells with surface projections and the usual ciliated cells arranged in a definite pattern (Figure 17). Corresponding region of the experimental embryo showed epithelial cells with abnormal surface projections. Ciliated cells were also abnormal (Figure 18). A more detailed view is presented in the Figures 19 and 20. Large 'ruffles' present on the cells from experimental embryo (Figure 20) were not at all observed in the controls.

The results presented herein clearly show that tidal inundation of the breeding pools will be detrimental to the embryos of *M. ornata*. Increased salinity of more than 30‰ concentration of sea water will either be fatal or it will cause abnormal development of the exposed embryos. Many aspects of salinity-caused abnormal development, such as prevention of swelling of perivitelline space, curved body axis, inhibition of hatching, etc. have been discussed earlier⁶ and need not be reiterated here. The purpose of the present paper is to discuss abnormal neurulation and related phenomena.

Figures 17–20. 17, Ectodermal cells on the trunk region of the control embryo. The typical pitted appearance and surface projections are apparent. Also note pattern of ciliated cells. Cell boundaries are the distinct white raised lines (see magnified view Figure 19). Scale bar = 50 μ m. 18, Markedly changed ectodermal cells of an experimental embryo. Note reduced ciliated cells and abnormal surface projections on many cells (magnified view Figure 20). Scale bar = 50 μ m. 19 and 20, Magnified views of Figures 17 and 18 respectively. Scale bar = 10 μ m.

Both processes, induction of neural tissue and morphogenesis of the neural tube, continue to attract the attention of research workers. A detailed review of recent advances in neural induction phenomena has recently been published⁹, while the mechanism of neurulation has been reviewed several times during the past 20 years or so by different workers^{10–12}. In addition, two excellent reviews of the experimental analysis of the shaping of the neural plate and tube are published by Jacobson^{13,14}. In spite of this, the actual nature of neural induction phenomenon and the mechanical as well as physiological aspects of neurulation are not fully understood.

As far as neurulation is concerned, there is still controversy regarding the forces involved in the rolling of neural folds to form the actual neural tube – whether the forces are entirely intrinsic (to the neural tissue) or extrinsic factors (nonneural ectoderm, mesoderm) also help the process¹². It is also becoming apparent now that

the mechanisms involved may be different along the antero-posterior axis of the neural tube^{12,14}. This may be the reason why only the anterior part of the nervous system was affected in our experiments. In fact, Burt¹⁵ also reported that neurulation was more retarded in the head region than in the spinal cord when the *Amblystoma* embryos were exposed to saline water. While studying the uptake of Ca^{++} in developing frog embryo, Barth and Barth¹⁶ also showed that cephalic regions incorporate more Ca^{++} than the spinal regions. In mouse, external Ca^{++} added in the medium was shown to augment the rate of neural tube closure in the hind brain region only and not in the other region, again pointing out that physiological mechanisms may be different at different places along the neuraxis¹⁷.

An interesting aspect of our finding is that the non-neural ectoderm got detached from the neural ectoderm, somewhere in the latter stages of neurulation, in the em-

bryos exposed to sea water. Apparently, in spite of detached ectoderm, neurulation continued, albeit abnormally. *Microhyla* embryos exposed to NaCl also show defective neurulation⁶, an observation in agreement with the present results. This is not surprising since the major cation in sea water is indeed sodium. It appears certain, therefore, that the concentration of cations/anions, especially that of sodium, in the water surrounding the embryos plays important role in morphogenesis. Exposure to cations like mercury and lead does not produce a similar effect in *Microhyla* embryos^{18,19}. The collapse of neural folds reported here is, however, very similar to that reported in rat embryos cultured in Ca⁺⁺-deficient medium²⁰. It may be worthwhile to investigate the effect of sea water/NaCl treatment on Ca⁺⁺ balance in *Microhyla* embryos and its relation with neurulation.

On the whole, the SEM structure of the control *Microhyla* neurula is similar to that described by Tarin²¹ and Löfberg²² for other amphibians. The surface ectoderm is showing all the features described by these authors. In experimental embryos, there were considerable cell surface alterations as a result of exposure to drastic change in the salinity. But the mechanism involved is unknown at present. Keller²³ has, however, noted that in *Xenopus* embryos high salinity (0.385% salt concentration) causes the epithelium to weaken and even break down. He further noted abnormal ingression of surface cells, thickening of blastula and gastrula walls as well as exogastrulation. However, we did not observe exogastrulation in the present study. This may be because we did not remove the vitelline membrane.

In conclusion, it can be stated that *Microhyla ornata* embryos will not tolerate excessive tidal inundation and the resultant increase in the salinity of their ambient pond water. The embryos are very sensitive to more than about 0.2% NaCl or 20% sea water and that high concentration of salt will cause abnormal development.

ACKNOWLEDGEMENTS. We are extremely grateful to Prof. Antone G. Jacobson, Center for Developmental Biology, Department of Zoology, University of Texas at Austin, Austin, USA, for his comments on the SEM pictures and suggestions on an earlier draft of this paper as well as for providing recent literature. Thanks are due to Mr R. K. Dongre for technical help with the SEM. This work was partially funded through grant no. SR/OY/Z-10/90 accorded to SG by the Department of Science and Technology, Government of India under 'Scheme for Young Scientists'.

Received 29 June 1996; accepted 16 July 1996

The Many Faces of Science: An Introduction to Scientists, Values and Society. Leslie Stevenson and Henry Byerly. Westview Press, 5500, Central Avenue, Boulder, Colorado 80301-2847, USA. 257 pp. Price: US \$18.95. Hard bound US \$55.

The sociologist Paul Feyerabend's scathing dismissal of science – 'What's so great about it?' – is countered in this mildly diverting but otherwise forgettable book by two professional philosophers. Although it is not specifically intended to be an apology for science, the book does have a superficially feel-good flavour that scientists afflicted by self-doubts about their calling might take some comfort in. The lay reader is unlikely to be similarly soothed, but he or she will probably come away from the book with a number of morsels of information that could confound dinner companions, or win quizz competitions. It is interesting to read, for instance, that Count Rumford (he of cannon-boring fame) was a sort of Yankee upstart with a taste in rich widows who has given us, among other things, the sofa bed and the drip coffee-maker. Aficionados of trivia may enjoy learning that Niels Bohr, an early and important contributor to quantum mechanics, came to the attention of the US Secret Service when he worked on the atomic bomb project and was code-named Nicholas Baker. But they might also echo T. S. Eliot's doleful enquiry: After such knowledge, what forgiveness? because, in the end, Stevenson's and Byerly's book does not really rise much above the level of a compendium of facts and anecdotes, some amusing, some bland. There is a marked reluctance to confront issues (despite the promise of the title), and much care to be evenhanded in all things, whether from pusillanimity or from political correctness is not clear. The book is also marred by some inaccuracies, and the occasional howler. For instance, as evidence of Isaac Newton's willingness to take pains, the authors point to his calculation, to 55 decimal places (!) – of the area under a curve by series expansion. What must surely be meant is his use of 55 terms in the expansion. Einstein's 1905 paper on Brownian motion is said to have supplied the definitive arguments for the physical existence of molecules, an ob-

servation unlikely to have received a ringing endorsement even from Einstein himself. And chemists will be non-plussed to set Gibbs phase rule described as a method to determine the concentrations of various substances so as to get a desired mixture in which the components are in equilibrium and do not separate out.

Symmetry Orbits. Hugo F. Verheyen. Birkhäuser Boston, 675 Massachusetts Avenue, Cambridge, MA 02139, USA. 1996. 236 pp. Price: DM138.

Texts on symmetry in the structure of objects used to be terse, abstract writings on a course of pure mathematics, even a few decades ago. The classic texts by Weyl and Hamermesh were beyond the reach of most physical scientists. There were hardly any illustrations. With the success of symmetry-based applications of quantum mechanics in understanding molecular structure and features of spectroscopy, a range of texts have appeared varying in their

audience level from an expert to a pedestrian. With greater access to computer graphics, more attractive illustrations were now expected.

It is in this aspect, namely the quality of illustrations, that the book *Symmetry Orbits* by Hugo F. Verheyen, comes out on top. It utilizes photographs of models, black and white computer graphics with excellent shading, as well as line drawings to help the reader in experiencing symmetry groups. The pictures are highly attractive and naturally demand attention. Unfortunately, having nearly 200 illustrations in a 234-page book imposes constraints on what else can be included in the text. There is an extensive classification of isometries and later, polyhedra, but in a language less familiar to a physical scientist. There are, perhaps for good reasons, no attempts to develop a theoretical framework to understand structural properties of objects like molecules. It seems that the author is more interested in involving the reader in the beauty and complexity of geometry than in discussing applications that follow from the occurrence of symmetry. To take an example, after reading this book, you can marvel at the beautiful design in the making of a fullerene molecule, that the molecular world indulges in; but to understand the role of symmetry in determining what internal modes will be accessible for interaction with the surroundings, one has to look for further texts.

Thus, the book is really meant for those who have a mathematician's interest in group theory. Thus, tetrahedral is A_4 and octahedral is S_4 . Of course, this does not reduce the value of the work, but it does limit the audience significantly. Unfortunately, the absence of an alphabetic index or a glossary makes it even more difficult for one more used to the Schoenflies symbols. The book is divided into two parts; the first with three chapters is titled 'Realization of Symmetry Groups' and the second with four chapters is called 'Compounds of Cubes'. Most of the text is on defining the terms and classifying various possibilities. The classification of the finite compounds of cubes is done in a very compact and yet exhaustive manner. The positions in an orientation with rotational freedom are worked out in detail and the angles are given to decimals of seconds.

Figure 1. The symmetry operation of the complete octahedral group ($S_4 \times I$ or O_h ; order 48; E, I, 23 rotations, 9 reflections, 14 rotating inversions). Each operation is shown in terms of equivalent number of reflections in an imaginary cube. A rotation, for instance, is a product of 2 reflections.

a

b

Figure 2a, b. Two positions of a $D_3 \times I$ group in its $C_3 \times I$ orientation, shown together as images of one another rotated through an angle of $22^\circ 14' 19''.52$. *a*, general view; *b*, along a threefold axis. A large number of such compounds (regular polyhedra with common centre) are introduced in the book for the first time.

Another perspective can come from artists or people who love activities like origami. In other words, the group theoretic insight can also mean for those

gifted in art, a rational outlook towards structured or not so structured design. To put it lightly, it could be interesting material for adults, who take toys seri-

ously. In chapter 7, titled 'Assembling Models', instructions are given on how to design 3-D models from cardboard pieces like a jigsaw puzzle. This is similar to constructing the Brillouin zones of a crystalline structure with the Miller planes clearly marked. This can indeed be a lot of fun.

There are a few things that should excite lovers of geometry. For instance, the photograph of a 2.3 metres high ball and stick model of platonic solids, that the author had made inspired by an old Dutch book written by H. Naber. The author's cat eventually brought this piece of art and mastery to extinction. A personal memoir of history leading to the publication of the book, in the appendix, is an interesting reading.

Genetics and Evolution of Aquatic Organisms. A. R. Beanmont ed. Chapman and Hall, Cheriton House, North Way, Andover, Hampshire SP10 5BE, UK. 1994. 539 pp. Price: not known.

Genetics – survey, inventories and experimentation – of aquatic organisms is rather a slow starter. Emphasis in the early 70s used to be on the measurement of genetic variations; its relationship to environmental variability; its maintenance by selection and its use in taxonomy. However with the emerging field of biotechnology, the technical advances in the study of genetics and the increasing dominance of neutral theory as the explanation for genetic variation at both the protein and DNA level, a major shift is discernible.

Out of 44 contributions under segregated titles, 24 relate to marine species, 10 to limnetic domain and the remaining 8 to aquatic environment in general. Large abundance with patchy distribution is a hallmark of aquatic organisms, more specifically the marine species. However, the paradox is that most species do not have enough genetic variations. Consequently, the intraspecific genetic diversities having discrepancies

of very high magnitude, between abundance and population size still remain unexplained.

Another unanswered question relates to large temporal variations, particularly in marine biota. In spite of high gene flow, genetic differentiation on spatial scale requires differential survival of genotype after recruitment from planktonic larval stock. Of course, the large variance in reproductive process is mediated by hydrographic regimes. Thus there is a strong and direct linkage between population genetics and environment. Further, the large variance in reproductive process also affects population structure because of temporal and spatial variations in the genetic composition of the recruiting larvae. So far, the impact of DNA technology in population genetics is less than projected.

Talking about the evolution, several sets of biochemical databases (allozyme, immunological and DNA – RNA hybridization) have been applied to collate phylogenetic relationship among aquatic species. In terms of tools, the advent of polymerase chain reaction (PCR) technique has generated large amount of information on DNA, especially in fin-fishes. The population genetics studies

on a wide range of agametic clones provide information on the evolutionary consequences of the basic differences between agametic clones in terms of genetic variability and extent of ecological differentiation. In this context, an unanswered question in chromosome genetics is 'do marine species frequently exhibit greater number of chromosomes than freshwater species?'

Genetic research complimentary to pollution monitoring programmes is becoming indispensable. Pollution-mediated mutations directly cause damage to the DNA molecule within the individual cell nucleus, resulting in gene mutation or chromosomal aberrations, though not much is on record about chromosomal aberrations. Another discernible influence of pollution is through selective pressure on the genetic structure of the population by modifying the environment. Heterozygote genotypes, because of their less energy demanding maintenance have better chances of survival in stressful environment.

Aquaculture has tremendous scope for genetic research, especially the quantitative genetics; chromosome ploidy manipulation; allozyme genetic and transgenic organisms. An important

observation is 'standard errors on heritability estimates are uncomfortably larger unless.... based on very large numbers'. Hybrids which are heterotic for growth and resistant to disease have to be the goal as evidence from the success of different strains of crabs and catfishes indicates. In spite of the inherent sterility of triploids, a promising approach is to induce tetraploidy by cell fusion. Rather a disheartening finding for fish farmers is the repeatedly significant loss of genetic diversity following hatchery culture. Studies on

effects of cultured fish on wild populations have demonstrated that in many cases, coadapted gene complexes may be broken down and unique alleles lost in wild population, following extensive hybridization and introgression of genes from cultured organisms. Transgenic involving DNA techniques is currently centered around transfection, i.e., the introduction of novel genes in aquaculture species. The number of genes which might be appropriate for genetic engineering in finfishes and several growth genes have now been identified and cloned.

The contents are mainly confined to reports from Europe. It warrants an early compilation of results from the rest of the world, so as to have a global perspective.

Indeed a good read.

NIMBKAR AGRICULTURAL RESEARCH INSTITUTE PHALTAN, MAHARASHTRA

NARI requires engineers and scientists to work in the area of innovative renewable energy R&D and commercialization, for rural areas. Positions are open in the areas of Biomass gasification; Development of new materials for thermoluminescent mantles and Solar detoxification of industrial wastewater.

Besides development of the technologies, selected candidates can also partake in their commercialization. NARI helps the entrepreneurs in this regard.

Qualifications

- a) B E/B Tech or M Tech in Mechanical, Chemical or Materials Engineering.
- b) Ph D in Physics or Chemistry.

Remuneration: Consolidated salary between Rs 6000 and Rs 10,000 per month depending on the qualifications and experience.

Please apply with detailed biodata and names of 3 references to:

Director, NARI
P.O. Box 44, Phaltan 415523

Some earthquakes of Kashmir from historical sources

R. N. Iyengar and Devendra Sharma

Collection of information on past earthquakes is essential for proper assessment of the seismicity of a region. Even though the Himalayan continental collision zone is known to be highly seismic, data on earthquakes prior to the eighteenth century are scarce. This may be contrasted with the Eurasian continental boundary zone, wherein past data have been pieced together¹ to go as far back as second century A.D. In recent years due to the increasing human intervention in the river valleys, there has been a heightened sensitivity towards seismic events occurring in the Himalayan region. A question of considerable engineering and scientific significance is the return period of large earthquakes in the Himalayas. Recently Athavale² has highlighted the use of historical records in improving our database on earthquakes in India. We attempt to bring here to the attention of the readers that reliable information is available about a few earthquakes in Kashmir.

History of kings of Kashmir³

Among the innumerable books that were written in Sanskrit language in medieval India, *Rajatarangini* occupies the pride of place as the only one which can be classified under History. The author of *Rajatarangini* is the famous Kalhana who lived in 12th century A.D. The author has attempted the genealogy of the kings of Kashmir starting from very early periods (2448 B.C.) up to 1148 A.D. Kalhana was a contemporary of king Sussala (1112–1127 A.D.) and king Sinhadeva who ascended the throne in 1127 A.D. Kalhana's narration has been continued by Jonaraja as *Rajavali* up to 1412 A.D. Srivara Pandit, a disciple of Jonaraja further covered the period up to 1477 A.D. The last and further part of the history is by Prajya Bhatta who has written *Rajavali Pitaka*. This gives the history of Kashmir up to 1587 A.D. when Akbar conquered the kingdom of Kashmir. All the above books have been translated into English by J. C. Dutt³.

A total of four earthquakes find mention in the history of Kashmir. The details are as follows.

Earthquakes in 12th century A.D.

Kalhana describes the reign of Sussala in great detail. Sussala lost the kingdom for a brief time and regained the same from Bhikshacara (Bhikshu). During his second reign, Sussala had to put down many rebellions and enemies. While the king's soldiers were engaged in battles with the followers of Bhikshu on the banks of river Kshiptika, Kalhana writes³: 'The Sun became fierce, there were earthquakes several times, and terrible storms blew breaking down many trees. The dust raised by the storms seemed like pillars raised to support the sky which was rent by blows.' The description is more graphic about the storm than about the earthquakes. However, Kalhana wrote this part of history pertaining to Sussala from personal knowledge and thus the occurrence of the above earthquakes near Srinagar (capital of the King) during 1121–1125 A.D. may be reliable.

Major earthquake in September–October 1554 A.D.

The most detailed description of an earthquake which occurred in the reign of king Shamsha Shah (1537–1559 A.D.) has been provided by Prajya Bhatta. The translation of Dutt³ is reproduced here: 'In the month of Ashvina of the year 30 there occurred frequent earthquakes on account of the wicked acts of the king, as if the earth suffered from flatulency. The planet which causes calamity is assuaged by various acts, by gifts of land to independent people, by giving back to men their properties which had been robbed, and by like deeds. Now there occurred an earthquake at the second watch of night when all men were asleep, and it destroyed many people. It caused holes

in the ground, and travellers going on their way were misled at every step. Houses fell into these holes at night and the people, anxious to get out from their houses in the morning, issued by breaking through the roof. On this occasion many wooden houses fell into the water of the Vitasta and when they had floated down for seven kroshas, the people who were in them awoke and came out. The confusion, caused by the earthquake in the towns of Hasainpura and Hosainpura, situated at some distance across the river, can be seen even to this day. Pitiabie cries of lamentation of the much afflicted people were then heard calling out "O father", "O mother!", "O friend", "O brother!" in different places, which made the heart feel as if it were struck by a thunderbolt. At this time the sky appeared terrible with the claps of thunder, the movements of the stars were stopped, and the land was agitated like a gourd on the waves. The mind of the people became troubled with the fear of the earthquake, and they felt no affection for sons or friends or wives or for good men or for kind-hearted people or for any object whatever. It was owing to the glory of the holy shrines of Vijayeshvara, Martanda, and Varahakshetra, that fears and apprehension from earthquake were not felt by the inhabitants of these places. The earthquake continued for several days, occurring several times every day, and all the people lived under canvas.'

Two minor shocks

Two earthquakes are passingly mentioned in the text. Both refer to the sixteenth century. The first was during the reign of Gazishah who ruled Kashmir for two years in 1560–1561 A.D. The text reads, 'The king saw conflagrations in different directions and there occurred earthquakes and so he took council of soothsayers....'.

The next event which from its description appears to be an earthquake has been described during the reign of Ali Shah (1569–1577 A.D.). The narra-

tion is as follows: 'But suddenly the sky became red on all sides, like the fierce fire that will appear at the end of the world; it prognosticated destruction by famine. The world showed symptoms of a calamity and trembled, as if unable to bear the weight of a famine.'

The famine is further described in detail. However the trembling of the earth mentioned may not be just figurative.

Conclusion

Search of historical literature and records gives valuable information regarding regional seismicity and may even help scientists in refining recurrence intervals of seismic activity. There are innumerable references and speculations about earthquakes in ancient and medieval Indian writings. But information on the dates and location of actual

shocks is not available. Thus, the description, provided by the historians of Kashmir, of the shock of 1554 A.D. is perhaps unique.

The Cambridge history of India in the chapter 'Kingdom of Kashmir' mentions a great earthquake which changed the course of river Jhelum. This is perhaps the same as the one described previously. Also this may be same as the 1552 A.D. Srinagar event listed in the earthquake catalogues. The description of the shaking: 'It caused holes in the ground and the land was agitated like a gourd on the waves The earthquake continued for several days, occurring several times every day.' indicates severe shaking with a main event of MMI intensity IX-X and Richter's magnitude reaching 7 or higher values. Cross references from other literary sources may throw more light on the felt area of the earthquake. All the places

mentioned in the text are identifiable. For example Varahakshetra or Varahmula, is the present day Baramulla. Hence palaeoseismic studies in the Kashmir valley will also prove to be valuable.

MEETINGS/SYMPOSIA/SEMINARS

20th International Congress of History of Science

Date: July 1997

Place: Liege, Belgium

The Indian National Science Academy plans to present at the Congress a Status Report on Studies in History of Science in India, covering the period 1993-1997. The National Committee for International Union of History and Philosophy of Science (IUHPS) requests individual researchers and institutions to finish brief reports on studies carried out in the field of history of science, from April 1993 to date. The report should be very concise and in third person so that an author's work is preferably reported in his own words. Offprints of papers on which the report is based as well as a list of publications for the period should also be sent. The institutions may like to send a consolidated report. They should provide the following information: 1. Book/monographs published; 2. Symposia, conferences, schools, etc. organized; 3. Library and archival services available; 4. Complete postal and e-mail address along with phone and fax numbers (including area code) for compilation of a directory. Material should reach before 30 September 1996 to:

National Symposium on Current Trends in Biochemistry and Biotechnology of Fungi

Date: 25-26 October 1996

Place: Hyderabad

Topics include: Fungal growth and metabolism (Solid-state and submerged fermentations, fungal enzymes of industrial importance, fungi in extreme environments, mechanisms of plant pathogenesis, biological control of pests using fungi, fungal diseases of human importance, secondary metabolism in fungi and fungal genetics); Fungal toxins (Mycotoxins, alkaloids, pigments, antibiotics and antimicrobial compounds, fungal toxins in animal and human health, methods for mycotoxin analysis, control strategies and management in agricultural commodities); Bioremediation by fungi, Degradation of toxic chemicals, pesticides and petrochemicals, biosorption and bioaccumulation of toxic metal ions and radioactive waste from effluents, recovery of precious metals and applications of fungal biosorbents.

JAWAHARLAL NEHRU CENTRE FOR ADVANCED SCIENTIFIC RESEARCH

JAKKUR P.O., BANGALORE 560 064

Advertisement No. 13/96 08.08.1996

Applications are invited for the post of **FACULTY FELLOW** in the pay scale of Rs 3700-5700 plus allowances in the following areas:

- i) Gene targetting and gene therapy
- ii) Molecular parasitology

Applications on a plain paper giving detailed curriculum vitae along with references may be sent to the Co-ordinator, Jawaharlal Nehru Centre for Advanced Scientific Research, Jakkur, Bangalore 560 064, so as to reach not later than **two weeks from the date of this advertisement.**

MINISTRY OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF SCIENCE AND TECHNOLOGY

JSPS RONPAKU (DISSERTATION PH D) PROGRAMME: 1997-98

Department of Science and Technology (DST) invites applications from promising and qualified young researchers for JSPS RONPAKU (Dissertation Ph D) Fellowships to Japan for 1997-98 offered by the Japan Society for the Promotion of Science (JSPS) within the framework of India-Japan Cooperative Science Programme (IJCSP). Four fellowships are available.

DESCRIPTION OF THE RONPAKU PROGRAMME

RONPAKU programme provides tutorial and financial support to researchers who wish to obtain their Ph D degrees from Japanese universities through the submission of a dissertation, without going through the course work.

Grantees under the RONPAKU programme are required to conduct their dissertation research under the joint supervision of a Japanese Advisor and an Indian Advisor. For this purpose, during the maximum period of five years, the RONPAKU Fellows will visit Japan once a year to conduct their research at a Japanese university/institute under the supervision of the Japanese Advisor who will visit the RONPAKU Fellow's country, when necessary, to supervise the research together with the Fellow's home Advisor.

FIELDS

All fields of Science and Technology

ELIGIBILITY

Applicant should

1. be a citizen of India;
2. be holding a regular position as a researcher in a recognized scientific institution in India;
3. have already achieved substantial research results and, through dissertation research under the programme, be deemed likely to obtain Ph D degree successfully;
4. be able to forward the final application through proper channel of the parent institution.

JAPANESE ADVISOR

The Japanese Advisor must be either a professor, associate professor or lecturer who teaches in a doctoral programme of either a national, public or private university in Japan.

SUPERVISION OF THE RESEARCH

During the overall tenure of 5 years the RONPAKU Fellow will visit Japan once a year for a maximum period of 90 days per visit to conduct research under the supervision of the Japanese Advisor. An extension of the Fellow's stay in Japan of up to 30 days may be approved in the final year of his/her fellowship tenure to obtain his/her Ph D degree.

The Japanese Advisor may visit the fellow's country, not more than once a year (for a period of 7–30 days per visit) to supervise the research in accordance with the plans approved.

TERMS OF AWARDS

JSPS provides the following financial support:

To the RONPAKU Fellow

1. Round-trip economy class air ticket between India and Japan;
2. Maintenance allowance as per the JSPS regulations;
3. In Japan research trip allowance of up to Y100, 000;
4. Sickness and accident insurance coverage during the stay in Japan as per JSPS regulations;
5. Expenses related to dissertation submission and publication in the final year of the fellowship tenure, as per JSPS regulations.

To the Japanese host

1. Round trip economy class air ticket between India and Japan;
2. Maintenance allowance for stay in India.
3. Supervising expenses (when receiving a RONPAKU Fellow);
4. Research allowance for supervising the RONPAKU Fellow;
5. Supervising expenses (when visiting Fellow's country)

GUIDELINES FOR SUBMISSION OF APPLICATION

The Application Forms can be obtained from the Programme Office, India–Japan Cooperative Science Programme (IJCSP), International Division, Department of Science & Technology, Technology Bhavan, New Mehrauli Road, New Delhi 110 016. Request for application should be received latest by September 15, 1996 along with a self-addressed envelope (12 cm x 27 cm) entitled 'JSPS RONPAKU Fellowship'. The duly filled in application form could be forwarded by the candidate through proper channel, as applicable to his/her parent institution.

Application complete in all respects should reach the above address latest by October 15, 1996.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted. Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally

not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21 × 28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The **title** should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, **60**, 355-362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319-322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

INDIAN COUNCIL OF AGRICULTURAL RESEARCH

The Indian Council of Agricultural Research, New Delhi announces the following existing and new awards:

Best Institution Award, 1996

In order to recognize the best performance in Agricultural Research and Education, three ICAR Awards of rupees one lakh each will be given to two ICAR Institute/N.R.C./Project Directorate and one state Agricultural University, partially out of the interest accrued from the King Baudouin Award bestowed on the ICAR in 1989. Those institutions which have received the award earlier in 1995 need not apply.

Vasant Rao Naik Award, 1996

All scientists or extension workers who have made outstanding contribution in the areas of Water Conservation and Dryland Farming in India shall be eligible for the award. One award of Rs 100,000 is to be given annually, for the work done during the preceding five years of the award.

Outstanding Women Agricultural Scientist Awards, 1996

All the women scientists working in the Institutions under the ICAR system including State Agricultural Universities are eligible for the award, one award of Rs 25,000 is to be given away annually for the significant contributions made during her career as an agricultural scientist.

Hari Om Ashram Trust Awards, 1995-96

All scientists engaged in research in the field of Crop Sciences, Horticulture, Resource Management and Animal Sciences in India shall be eligible for the award. Four awards of the value of Rs 20,000 each are to be given once in two years, for the work done during the preceding five years of the period of the award.

ICAR Young Scientist Award for Agricultural Research, 1996-97

All young Scientists/Lecturers/Assistant Professors and who have obtained the Ph D degree and are below the age of 35 years shall be eligible for the Award which will consist of the sanction of a really challenging scheme to be submitted by the candidate and a cash prize of Rs 10,000, 50 per cent of which will be given at the time of the award of research grant and the remaining 50 per cent will be released on the successful outcome of the scheme. A total of 10 awards will be made in various disciplines of agricultural and allied sciences once in two years.

ICAR Awards for Team Research, 1994-96

All the persons engaged in research in the field of agriculture animal husbandry and fisheries sciences in India shall be eligible for the award. Eight awards of Rs 50,000 each are to be given once in three years for the work done during the preceding three years of the period of the award.

Dr Rajendra Awards, 1994-96

The award is open to Indian authors including Editors of multi-author book where the Editor has himself contributed substantially together with an editorial preface. Both published works and manuscripts proposed to be published by its author will be accepted provided that such a work is written originally in Hindi and does not infringe the copyright of any other person. Eight Awards of Rs 20,000 each are to be given once in three years for the work done during the preceding one year of the period of the award.

The application form for the above awards may be obtained from **Dr R. C. Maheshwari, Assistant Director General (CSC), ICAR, Krishi Bhawan, Dr Rajendra Prasad Road, New Delhi 110 001 on or before 31 October 1996** by sending a self-addressed two-rupee stamped envelope. Six copies of the application may be forwarded by the Head of the Institution/Directors of Institutes/State Department of Agriculture/Horticulture/Animal Science/Fisheries and Vice-Chancellors of State Agricultural Universities. **The last date for submission of applications for these awards is 16 December 1996.** The last date for candidates in the Andaman and Nicobar Islands, Lakshadweep States, Union Territory in the North Eastern Region, Ladakh Division of J&K State and Sikkim is 31 December 1996.

Gene therapy

Curing diseases or playing God? Luddites often wrongly frame the question in this manner. Genetic manipulation of organisms, using recombinant DNA methods, is now commonplace. Rapid advances in technology and in our understanding of the mechanisms underlying many diseases allow us to realistically consider methods which alter human DNA to treat illnesses. Should we permit such approaches to medical treatment? Is it safe? What are the ethical implications? Are we playing with Nature when we alter an organism's DNA? Will we create a monster we cannot handle? There is only one answer to all these rather complicated questions: The application of recombinant DNA techniques to medicine, farming, industry, etc. does indeed raise important ethical, social and legal issues. The extent to which answers are known, the implications and the issues all vary from case to case and even with the social context. General answers are not only not possible, particular answers will change rapidly with time. In this situation, the only solution is for biologists to be in constant open communication with their societies so that an ongoing discussion with doctors, lawyers, social leaders, politicians and the lay public is always maintained. Decisions about what is possible and desirable should therefore be based on informed consensus. The credibility and openness of the scientific community is essential if medical science is to benefit from the immense possibilities becoming available.

The situation in many societies, including ours, is unfortunately quite the opposite. Post-World War II euphoria about science as the vehicle for eradication of poverty has

given way to suspicion of technology. We are often asked to choose between economic development and the rape of the environment as if one must live in tribal splendour, at one with Mother Earth, or face the wrath of the Gods for daring to alter Nature. As a society, we must accept informed debate as a method for reaching agreement and as scientists we must place technical facts in an accessible form and appreciate concerns of social and cultural origins without being dismissive of them.

Let us take specific examples. Duchenne's muscular dystrophy is a sex-linked disease found in India and in the rest of the world. The gene responsible for the disease has been identified and studied in great detail. It is possible to rather easily diagnose if a developing foetus is male and carries the mutant gene. The human who develops with this defect will surely die early in his youth and will suffer greatly. If it were possible to inject his muscle cells with targeted DNA encoding the normal gene product, so that he is 'cured' and leads a relatively normal life, is it ethical? After all, we give thalassemics blood transfusions, can we not inject into the developing foetus genes which allow them to make normal blood, but do not affect them in any other way? Many biologists will give a qualified yes to these questions, their views depending on the exact method proposed. Many religious and social leaders may object, on the ground that one should not interfere with a developing foetus.

A critical requirement for informed debate on these questions is the availability of facts to discuss potential risks and possibilities. Facts alone are not enough to convince our societies about specific scientific agendas, but facts are es-

sential. And facts on the possibilities can be available only by experiments on model organisms. Gene replacement is possible and has been done effectively in bacteria and yeast and is possible in animals such as mouse. Foreign genes have been introduced in a variety of organisms ranging from bacteria, plants and animals. These studies have allowed a rational analysis of specific possibilities of gene therapy in human. However, much needs to be learnt about how DNA-based therapy can be performed in human. What are the vehicles of delivery of the DNA? How will the DNA be targeted? How will it express in the required amount in the correct tissue and developmental stage? Rangarajan and Padmanaban (page 360) address these questions by reviewing rodent models for gene therapy and comparing them to what is possible in human. They present an analysis of their experimental approaches and possibilities. Comments on their report and similar reports from people studying other aspects of medical applications of modern biology should allow discussions to begin on an important issue.

K. VijayRaghavan

Soaps and history

Every child (and adult) who has blown soap bubbles will bear testimony to the marvellous properties of surfactants (a name derived from the term *surface active agents*). From soaps and detergents to emulsifiers and foaming agents, surface active molecules find myriad applications, that permeate almost every aspect of daily life. In biology, the wonderfully fashioned architecture of cell and organelle membranes relies on the lipid bilayer; a superb example of self-organization driven

CORRESPONDENCE

ther stated that 'leaving the work of the institutions in the hands of older scientists may reduce the overall viability of Indian research'.

In any organization, if old age has hindered or adversely affected the innovativeness and or creativity, then to uphold discipline among the scientific community, the policy of promotion or recruitment has to be suitably amended. Further, the performance and contribu-

tions of scientists, irrespective of their positions are to be rigidly and periodically reviewed.

However, in this regard, it is imperative to remind ourselves that the *present young* will be the *future old*. A scientist whether young or old should be in quest of truth and knowledge. In various disciplines, many of the theories and hypotheses, put forth by the earlier scientists have even to this day remained as the basis for any

future studies. Let us salute the profound knowledge and insight of the old guardians of science!

Uncommon opportunities for a food secure world

There can be nothing more urgent than ensuring a food-and-nutrition-secure world where all of humanity will have enough to eat and be free from malnutrition now and in the future. This, however, is a formidable task. Attempts made in the past have not yielded the desired results. The situation continues to be one of deep concern. It is to tackle this problem that the FAO, which has been continuously addressing the question of feeding the world for the past more than 50 years, is convening the world food summit, a high level meeting of Heads of State and Heads of Government, in Rome during 13-17 November 1996.

Many of our resources - aquifers and the ozone cover, for example - are being depleted unsustainably. The natural-biological resource base has steadily deteriorated. Loss of biodiversity, soil erosion and desertification have gradually reduced the productive capacity of agricultural land. In some cases, this process has become irreversible, pointed out Elizabeth Dowdeswell, Executive Director, UNEP. 'The earth's capacity to produce enough food to satisfy our expanding demand is now emerging as the overriding environmental issue as the world approaches the 21st century', says Lester Brown of the World Watch Institute. And 'food security' is just one, albeit the major, component in the ongoing population-resource debate. There are other factors such as unprecedented demand for energy and other resources, quality of life, technological options, political freedoms, economic arrangements,

notions of justice and equity, and living in peace with other creatures with whom we share the planet.

Thus the tasks confronting humanity today are mammoth and complex and call for concerted effort of people from different streams of life. Surely, science has to play a crucial and central role if the desired goals are to be achieved. It is with this conviction that several Science Academies of the world decided to pool their collective wisdom to address the major issues of food and nutrition security and prepare a work agenda to be placed before the November Summit of political leaders.

The initiative came from the National Academy of Agricultural Sciences of India, Accademia Nazionale Delle Scienze, Rome, and the Third World Academy of Sciences, Trieste, to organize a four-day Science Academies Summit to reflect as scientists on the theme of 'sustainable food security' and to delineate the role of science and scientists in ensuring a balanced food basket for an ever-increasing population. This meeting was supported by Food and Agriculture Organization (FAO), Ministry of Foreign Affairs, Government of Italy, United Nations Development Programme (UNDP), and the Encyclopaedia of Life Support Systems (EOLSS).

At the Science Summit convened at the M.S. Swaminathan Research Foundation, Madras, during July 8-11, 1996, there were representatives of fifteen Science Academies including the Caribbean and Chinese Academies as well as the

Academies of Kenya, Uganda, Hungary, Lithuania and Pakistan, and international organizations including FAO, UNDP, UNEP, UNESCO, and CGIAR. The meeting was addressed by, among others, Gaetano Zucconi, Italian Ambassador to India, Ministers of the Government of India Chaturanan Mishra and Yogendra Alagh, elder statesman C. Subramaniam, and Tamil Nadu's Minister for Agriculture Veerapandi Arumugam.

The summit commenced with welcome addresses delivered by M. S. Swaminathan, President of the National Academy of Agricultural Sciences of India, G. T. Scarascia Mugnozza, President of the National Academy of Sciences of Italy, Johanna Dobereiner of the Third World Academy of Sciences, Peter Rosenegger, FAO Representative for India and Bhutan, and Hans-C. von Sponeck, Resident Representative of UNDP in India.

Y. K. Alagh, Minister for Planning and Science and Technology, reiterated the need for comprehensive measures that would ensure long term sustainability and said short-run crisis management would only lead to serious adverse consequences. Recognizing the key role of information dissemination, he emphasized the need to adapt the extension system for it to be able to convey the tremendous technological developments that are taking place now. He would also like to have in place a good system of patenting indigenous innovations that would make them freely available to the local people. For his part, the Union Minister for Agriculture,

Mishra, pleased the scientists assembled telling them that governments should invest a high percentage of their GDP on agricultural research. For example, he would like India to invest at least 1.0% as against 0.3% of GDP being spent now. Another suggestion he made was to have a system of social audit of research institutions.

While the Minister's ideas on government support are surely welcome, Elizabeth Dowdeswell felt that we must not depend upon the government for everything and we should also win the support of the private sector. There can be no talk of sustainability until the disparities in patterns of economic growth and consumption have narrowed. Women, in particular, have been marginalized by resettlement schemes and land tenure policies that emphasize male households. There should be a gender assessment study of each project going on farm, said Dowdeswell.

Food security is not a static concept and it changes with new life styles and new human habits. So do the tools to achieve it, pointed out Adnan Badran, Deputy Director General, UNESCO. Food security, thanks to the ongoing revolution in genetic engineering, will soon be determined on the lab-bench by interdisciplinary programmes yielding new strains resistant to diseases and insects and high protein diets from organic compounds produced biologically from algae, fungi, bacteria or synthetic hydrocarbons. Badran drew attention to the tremendous North-South disparities in the number of scientists and in the expenditure on Research and Development. He highlighted the different ways scientific research can help achieve food security, such as molecular biological research on agronomic, horticultural plants and animal husbandry to increase the yield, and R&D in genetic engineering for (a) high yield strains, (b) new crops, (c) resistant varieties to disease and insects, (d) dwarf varieties for intensive crop production, (e) post harvest longevity, (f) augmenting quality to consumer taste, and (g) adaptability to stress physiology.

Iba Kone strongly felt that the use or transformation of DNA strains for any purpose other than the benefit of humanity should be outlawed by the International Court of Justice at The Hague. Ismail Serageldin, Chairman, CGIAR, was concerned that the tremendous North-South

knowledge gap could lead to a new class of scientific apartheid.

Johanna Dobereiner emphasized the urgent need to establish regional centres of excellence dedicated to high quality training and research in critical fields such as food crops, agroforestry, agronomy, agrometeorology, soil and water management, and pest control in ecologically complex and fragile regions, and in the fields of molecular biology, genetic engineering, biotechnology and informatics. In her view, the success of India's Green Revolution has clearly established agricultural research as a major contributing factor in enhancing food security. She pleaded for greater North-South cooperation in research as well as fruitful industry-research-farmer interactions. It is important, she said, to develop fuel from bio-mass as has been done in Brazil and to select appropriate high-yielding varieties that would not need high doses of fertilizers.

R. S. Paroda, Secretary, Department of Agricultural Research and Education, Government of India, highlighted the tasks involved in Eco-regional Research and Development, such as identifying and prioritizing research issues common to different ecoregions and developing mechanisms for collaborative programmes involving National and International Agricultural Research Systems, FAO, UNDP, donors and NGOs as well as monitoring the improvements in the eco-region according to predetermined sustainability criteria. On the management issue, he emphasized the need for research on (i) the conservation and management of eco-systems that include multi-crop integrated farming systems in a programme mode, (ii) the management of production systems, and (iii) factors affecting farmers' incentives and adoption of improved technologies.

Jyoti Parekh, from Indira Gandhi Institute of Development Research, spoke on the importance of developing environmental auditing approaches and constructing environmental indicators. She suggested that environmentally sound farm management practices should be rewarded.

B. K. Sinha opined that food technology should play a greater role in popularizing coarse grains and root and tuber crops. Clement Sankat also thought that there is a need for us to shift our focus from cereal grains, rice, wheat and maize to

less exploited crops like roots and tubers, pulses (pigeon pea), oilseeds, fruits (Sapodilla, Cassava and Carambola), herbs and spices (Coriander). Self-sufficiency of individual countries or by a group of nations in a region with a consideration of climatic conditions may provide a stronger basis for food security of developing countries.

Obaidullah Khan of FAO could not agree any less with Y. K. Alagh in the need for winning recognition for the concept of community knowledge which is currently being threatened by the IPR regime. An underlying hard political issue of rural societies is the participatory control of and access to natural resources by those who are dependent on those resources. Another area of concern is the inadequate use made of the distinctive knowledge of women as far as food security and biodiversity are concerned.

Dominic Makawiti of the Kenyan National Academy of Sciences would like traditional foods made of highly nutritious and drought-resistant millet, sorghum and cassava to be revived and popularized through education. Hotels and restaurants, he said, should present traditional foods in a modern way that would make them more palatable. He would also like the public to be made guardians of the local environment.

An overview of what modern science can do to the improvement of post production systems was provided by Joseph Hulse. The possibility of using mathematical models and computer technologies in determining efficient means of placing and integrating all the components essential to safe and efficient preservation, transformation, distribution and marketing from rural and maritime producers and harvesters to urban markets and consumers is indeed attractive. He would like the National Agricultural Research Systems to be strengthened and the CGIAR Centres to pursue a policy of subcontracting many of their present responsibilities and activities to NARS and regional research networks.

While most of the Science Summit was concerned about what science and technology could do, Amir Muhammed, President, Pakistan Academy of Sciences, went beyond science and technology and emphasized the need to bring in management techniques to agriculture, to involve social scientists and to give highest priority to land reforms, streamlining land records, land consolidation and land tenure.

The Science Summit brought into sharp focus the urgent need to address the issue of food security with all the knowledge and skills at our command. The meeting threw up several cases from actual successful experiences worldwide and emphasized the need to blend the traditional agricultural practices with what modern biotechnology has to offer. What we need, probably, is a people-oriented

Super Green Revolution that can ensure all the benefits of the Green Revolution on a global scale minus its environmentally harmful effects, and at the same time make economic sense. We need a research agenda that integrates sustainable development, food security and the environmental concerns.

The mood is one of cautious optimism. While the tasks facing us look daunting,

it is felt that one can win the battle with an appropriate blend of scientific and technological inputs and conducive public policies.

Ruchi Bhandari and Subbiah Arunachalam, M.S. Swaminathan Research Foundation, Madras 600 113, India.

Madras Declaration of the Science Academies Summit

The text of the declaration adopted at the Science Academies Summit convened at the M.S. Swaminathan Research Foundation, Madras, during 8-11 July 1996, is reproduced below.

We, the participants of the Science Academies Summit, call upon the world leaders assembling at the World Food Summit convened by FAO in Rome in November 1996 to adopt this agenda as a means of harnessing science and technology for the transformation of agriculture into a primary instrument of a global *Evergreen Revolution*. Based on the principles of ecology, social equity, energy efficiency, employment generation and economic viability, this revolution will provide the technical foundation for the universal eradication of hunger and achievement of a food and nutrition secure world for all. At the same time, we wish to emphasize the urgent need for adaption, particularly by developing countries, of population policies which can ensure that children are born for happiness and not for mere existence.

A new revolution in agriculture

In the over 50 years since FAO took up the challenge of 'food for all', never before has science offered greater opportunity to achieve this goal for even the poorest of the poor. Scale-neutral innovations including those emerging from the fields of biotechnology and information technology, as well as the holistic management systems of soil health care, conjunctive water use, integrated pest management and integrated intensive farming systems represent only a few of the new opportunities to reach the nearly 800 million people lacking adequate nutrition.

Tapping this unprecedented potential will depend upon strengthening the capacity of national agricultural research and development systems to respond to

these new challenges with creativity. Therefore, we urge world leaders to reverse the global trend of disinvestment in agricultural research and development, convinced that such short-sighted policy can but only have tragic results. At the same time, limited resources make prioritization of research initiatives essential, and it is intended that this agenda assist political leaders in that task.

Meeting the challenge of increasing food availability now and in the future demands equal focus on production systems and on the larger issues of access to food. Therefore, science must work in partnership with farmers to create a new agriculture. An Evergreen Revolution must bridge the gap between the past's gains in production and the persistent need for reliable access to food by all. This will require a number of innovative approaches, including:

- Transformation of the most marginalized farmers of the world into agents of poverty alleviation and environmental management through the blending of traditional and frontier technologies in socially equitable, economically viable and environmentally sustainable *ecotechnologies*.
- Production of more food from a diminishing resource base, requiring new agricultural technologies and management systems providing *increased productivity* per unit of land, water, energy, labour and investment. Part of this will involve focussing research on neglected crops such as minor millets, grain legumes and tubers which can perform in times of environmental stress and in neglected areas such as arid and semi-arid coastal and mountain areas.

- A *systems approach* marshalling the combined and coordinated efforts of physical scientists and agricultural researchers, as well as systems analysts, mathematicians and social scientists. While agricultural production will remain the foundation of food and nutrition security, the larger scientific framework must integrate post-harvest technology, distribution systems and rural development, as well as economic and social empowerment of the poor, especially women. This holistic approach must also be taken in restructuring administrative systems, leading to a high degree of professionalism of such services.

Eliminating hunger among the poor of all nations will depend upon tapping the new opportunities offered in these *unconventional approaches*. Such *uncommon opportunities* are rooted in a new and broader conception of food and nutrition security which integrates multiple physical, social, economic and environmental dimensions.

National policies for sustainable food and nutrition security should ensure

- that every individual has the *physical, economic, social and environmental access* to balanced diet that includes the necessary macro- and micro-nutrients, safe drinking water, sanitation, environmental hygiene, primary health care and education so as to lead a healthy and productive life.
- that food originates from efficient and *environmentally benign production technologies* that conserve and enhance the natural resource base of crops, animal

husbandry, forestry, inland and marine fisheries.

The principle operational implications of the above mission statement are the following:

1. The *physical dimensions* of food and nutrition security will involve a transition from chemical- and machinery-intensive to knowledge- and labour-intensive farming technologies.
2. The *economic dimensions* of food and nutrition security require the promotion of sustainable livelihoods through multiple income-earning opportunities, such as crop-livestock-fish integration and agro-processing and agri-business.
3. The *social dimensions* of food and nutrition require addressing gender, class and ethnic discrimination against marginalized sectors of society, who consequently tend to be the most food and nutritionally insecure.
4. The *environmental dimensions* of food and nutrition security involve attention to soil health care, water harvesting management and the conservation of biodiversity, as well as to sanitation, environmental hygiene, primary health care and education.

Ultimately, self-reliance and skill- and labour-intensive technology must be the basis of food and nutrition security. As agriculture provides most of the jobs in many developing countries, the import of food by these nations would be equivalent to importing unemployment.

A ten point scientific and public policy agenda for sustainable food and nutrition security

The following ten-point agenda can provide the basic scientific and policy framework for achieving sustainable food and nutrition security at both national and international levels.

1. *An Evergreen Revolution must increase output in an economically viable, socially equitable and environmentally sustainable manner*, focusing on the food and nutritional supply system as a whole. Beyond investing in new scientific technologies, this will require public policies which provide a supportive economic and social environment.
2. *Science and technology for public good is the key to improving agricultural productivity among the poor*. With the spread

of free-market and intellectual property rights culture, it is essential that science designed for the public good receives adequate political and financial support. Scientists working in the areas of food and health security should regard themselves as trustees of their intellectual property.

3. *Sound environmental policies must provide the foundation of agricultural sustainability*. Therefore, a national Natural Resources Conservation and Enhancement Strategy will be fundamental to a National Food Security System. High priority must go to combating desertification and deforestation, and to restoring degraded land.

4. *Entitlements, asset reform and technological empowerment of the poor will be essential in ensuring economic access to balanced diets*, and would help address the triple goals of natural resources conservation, poverty alleviation and food security.

5. *The gender perspective must be integrated into technological development and dissemination*. A gender code, to identify and evaluate actions that ensure equity in food and nutrition security, should become an integral part of agricultural research programmes.

6. *Agriculture must serve as an instrument of income and livelihood opportunity as well as of food production*. Therefore, it is important that the economic benefits of agroprocessing and agribusiness are taken to poor families through rural value added enterprises and partnerships with the private sector.

7. *Macro-economic policies in the areas of pricing, trade and investment should be based on both environmental sustainability, as well as gender and social equity*. A systems approach must be taken, with a holistic view of production, distribution and consumption.

8. *The information age has provided tools such as the Internet and GIS mapping to promote a learning revolution in agriculture*. Extension information should be disseminated through computer-aided information shops operated by village youth. Vocational polytechnic institutes may be established for the rural poor.

9. *Existing global conventions must be implemented*, including those on climate, biodiversity, desertification and the oceans, as well as Agenda 21 of UNCED and the global plans of action on population, gender, habitats, social development and plant genetic resources.

10. *Public policies for sustainable food and nutrition security must institutionalize procedures to focus on both production and access*. To achieve the above, it will be prudent to develop legislation based on the following principles:

A. *National Sustainable Food and Livelihood Security Act*, including provisions for:

- Promoting policies which can help to achieve a balance between human and animal populations and the supporting capacity of the eco-system.
- Promoting conservation and enhancement of the natural resource base.
- Rehabilitating degraded soil, forests and aquatic resources, and introducing scientific land and water use policies.
- Ensuring economic and social access to food through steps which can enhance the livelihood security of the rural and urban poor, with special attention being given to children, orphans and women.
- Improving the biological absorption and retention of food through attention to sanitation, environmental hygiene and primary health care.
- Ensuring universal literacy and technicity (i.e. imparting new technical skills through learning by doing) for both men and women at the village level.
- Promoting the development and dissemination of ecotechnologies at the production and post-harvest phases of farming, with special attention to waste treatment and recycling.
- Improving post-harvest technology including storage, non-CFC-based refrigeration, packing with biodegradable material and efficient transportation and delivery.
- Establishing input and output pricing and credit and insurance policies which can help all farm families, irrespective of their innate input-mobilizing and risk-taking capacity, to benefit from new technologies and marketing opportunities.
- Building and maintaining grain reserves and operating an efficient public distribution system for making essential commodities available at affordable prices to the poor.
- Developing a *Hunger-Free Area Programme* in cooperation with local communities in order to demonstrate that chronic hunger and malnutrition can be overcome speedily by creating an enabling environment, where every individual earns his or her daily bread.

B. Implementing the equity provisions of the Biodiversity Convention

Industrialized nations should contribute 0.01% additional ODA for the purpose of being credited to a Global Fund for Biodiversity for Sustainable Food Security. Such a fund can be handled as a trust fund under the Global Environment Facility (GEF) for implementing the Global Plan of Action adopted at the International Technical Conference on Plant Genetic Resources held at Leipzig in June, 1996, and for recognizing and rewarding the contributions of indigenous and rural women and men to the conservation and enhancement of biodiversity, that is, Farmers' Rights. It should also be used to safeguard all mega-biodiversity areas as well as 'hot-spot' locations with reference to threats to biodiversity, ranging from landscapes to individual species. In addition, for this purpose developing nations rich in agrobiodiversity should levy a 1% cess on all agricultural produce for being credited

to a National Community Gene Fund to be used to recognize and reward the contributions of tribal and rural families to the *in-situ* conservation and enhancement of agro-biodiversity. Such steps will help to restore and revitalize the on-farm genetic conservation and selection-traditions of rural communities.

The role of the international community

To maximize efficiency and return on investment in the Evergreen Revolution, south-south partnership and cooperation in research and development will be essential, especially among nations with related agroecologies. The CGIAR centres should support these emerging regional networks and national systems, pursuing a policy of subcontracting present responsibilities as appropriate. We, the Summit participants, resolve to establish an *International Scientific Steering Committee for Sustainable Food and Nutrition Security*, to provide political leaders with

the scientific framework necessary to achieve food for all. Broader consensus can be fostered through a *Global Coalition for Sustainable Food Security* including farmers' organizations, civil society, academia, corporate sector, service organizations and mass media.

To convert the rhetoric of 'food for all' into reality within a specified time frame, we urge the G-7 and G-15 countries to jointly establish a high level *Steering Committee for Sustainable Food and Nutrition Security*, for which FAO could provide the Secretariat. This unique political body would be fundamental in reaching the shared goals of global food and environmental security, reduced need for emergency aid, enhanced political stability and the development of new markets for trade. This is a responsibility which the political leaders of the G-7 and G-15 countries must accept at the November, 1996, World Food Summit, if we are to enter the new millennium with hopes for a new humane world.

The 11th Himalaya-Karakoram-Tibet Workshop: Conference report

The Himalaya-Karakoram-Tibet (H-K-T) Workshops, held annually since 1985, are a timely response to the growing interest among the international geological community in the Himalaya-Tibetan region (see Sorkhabi¹ for a report on the 10th H-K-T Workshop in Switzerland). These annual meetings are part of an international 'boom', which has made the Himalaya-Tibetan region probably the most prolific field of geologic research among the mountainous terrains of the world. The recent boom in the Himalaya-Tibetan geology is a continual part of more than 150 years of geoscientific research in the Himalaya and south Asia. However, the present diversity and extent of international involvement in the Himalaya-Tibetan geology is unprecedented. The aim of this Himalaya-Tibet saga is no less than unravelling the 'biggest tectonic puzzle of Cenozoic Earth'.

Unlike Britain and continental Europe, whose tradition of geological research in the Himalaya dates back to the first half of the 19th century, North America is relatively a newcomer to the scene. The

first and the only American to have lived and worked in the Himalaya during the 19th century was Alexander Gardiner (1785-1877). Gardiner worked as an army officer in the forces of several kings in Kashmir. His wanderings and missions took him to all of the mountain ranges of the western Himalaya and the Pamir before any European explorer knew of these places. However, Gardiner did not document his observations and travels as a contribution to geographic knowledge².

The 1930s may be regarded as the 'initial pulse' of American studies in the Himalayan region. Helmut de Terra, a German geologist who had immigrated to the US and joined the Carnegie Institution of Washington, carried out pioneering research on the Quaternary geology of the west Himalayan foothills. In the same decade, G. Edwards Lewis and Paul D. Krynine at Yale University began research on the Siwalik formations; the Yale tradition in Siwalik studies (such as the palaeontological work of David Pilbeam) continued through the 1980s. Also in the 1930s, Edwin Colbert exam-

ined the Siwalik vertebrate fossil collection at the American Museum of Natural History in New York.

The 'plate tectonic revolution' of the 1960s motivated tectonic studies of the Himalaya and Tibet as this region came to be regarded as a 'type example' of continent-continent collisional orogenesis. Initially these studies were of 'armchair geophysics' genre, using seismic data and tectonic modelling. Over the past two decades, several institutions in the US have carried out field-based studies in the Himalaya and Tibet, resulting in an increasing number of graduate dissertations. Some of these active groups are those at Dartmouth College (where the late Noye Johnson with his students and colleagues carried out intensive research on the Siwalik Group of Pakistan), Orogen State University, Cornell University, Massachusetts Institute of Technology, University of California and University of Southern California (both at Los Angeles), etc. In addition, there are many individual Himalayan researchers scattered throughout North America. In recent years,

numerous sessions and symposia devoted to the Himalaya and Asia have been held at the annual meetings of American Geophysical Union and Geological Society of America. The US National Science Foundation has also funded numerous research projects on the Himalaya.

The 11th H-K-T Workshop, held at the Du Bois Center of the Northern Arizona University in Flagstaff (Arizona) from April 28 to May 2, 1996, was the first H-K-T Workshop in North America. It was a logical outcome of the increasing involvement of American geoscientists in the Himalaya-Tibetan region. Organized by Allison Macfarlane (George Mason University), Rasoul Sorkhabi (Arizona State University), and Jay Quade (University of Arizona), the Arizona workshop was attended by a total of 115 persons from various countries. Figure 1 shows the geographic distribution of the participants.

Before the workshop began, a one-day field excursion was made to the Grand Canyon on April 28; it was guided by Troy Péwé and Edmund Stump of Arizona State University. After the workshop, another field excursion was made from Flagstaff to Phoenix on May 2. Guided by Stephen Reynolds of Arizona State University, this field excursion was meant to show some geological features of the Basin-and-Range province of Arizona. Each of the field excursions was attended by about 50 people.

The three-day workshop covered various aspects of geological sciences of the Himalayan mountains and the Tibetan Plateau. The morning sessions were devoted to special topics.

Figure 1. Geographic distribution of the participants at the 11th Himalaya-Karakoram-Tibet Workshop, USA.

The first special session (on 29 April) was on 'Geodynamic models of the Himalaya and Tibet'. From a geological point of view, the Himalaya-Tibetan region is a massive stress system on earth brought about by the head-on collision of the Indian continental plate with Asia during Cenozoic times. While the plate tectonic framework is generally accepted, details of the tectonic evolution and geological processes shaping the Himalaya and Tibet are far from clear. Since India collided with Asia 55 ± 10 million years ago, India has penetrated into Asia for about 3000 metres³. Some of the intriguing questions concern this 'missing continental crust': Was the crust simply shortened by folding and thrusting, and this deformation distributed throughout the Himalaya as well as the entire Tibet? Has the Indochina block (in southeast Asia) extruded southeastward out of the way of an Indian indenter, and thus opened space for the northward motion of India? Has the Indian crust subducted beneath the Tibetan Plateau, thus forming a double-normal thick continental crust? Or has a combination of all these processes taken place? If so, how to quantify their relative dominance in space and through time? Closely linked with the problem of the 'missing continental crust', there is another set of questions concerning the 'uplift of the Roof of the World', which the Himalaya-Tibetan region represents: How and when did the Himalaya and Tibet uplift? What is the nature of lithosphere-aesthenosphere interactions beneath Tibet? Is a hot spot trapped beneath Tibet, thus deriving its thermal uplift as well as crustal extension? In attempts to answer these questions, several tectonic models have been proposed. Speakers in the first special session explored some of these models, and presented new data and ideas. Compared to the 1960s, when plate tectonics was emerging, great progress has been made in obtaining geophysical, geochemical, and geochronological and other quantitative data. Some of the exciting results come from deep seismic crustal profiles of southern Tibet carried out by a US-Chinese collaborative project called INDEPTH (International Deep Profiling of Tibet and the Himalaya)⁴. However, to work out definite, detailed geological scenarios of the Himalaya and Tibet, the ratio of speculation/fact is still high, and we need more data from various sectors

of this vast, less accessible region.

The Himalayan region is sometimes described by geologists as a 'natural laboratory'. They are mountains in the making by vigorous tectonic forces and in the shaping by powerful denudation agents. This provides a common ground for geoscientists in the fields of Quaternary geology, neotectonics and geomorphology to investigate the interactions of tectonic and geomorphic processes in the Himalaya. The second special session (on April 30) focused on the 'Neotectonic and Quaternary geology of the Himalaya and Tibet'. Topics covered in this session included: Applications of global positioning system to quantify the ongoing convergence between India and Asia⁵; determining the recent uplift rates of the Himalaya both from geophysical modelling and direct geodetic measurements; seismic activity (both palaeoseismicity and monitoring of current earthquakes); geomorphic analysis of mountain terrains by space-based imagery techniques; understanding the role of tectonic activities in the geomorphic development of river systems; determining exposure rates of rocks by cosmogenic nuclides; mass wasting and mountain slope processes; mapping and monitoring the dynamics of glaciers; studies of loess; late Cenozoic glaciation record in the Himalaya and Tibet. These topics are not purely scientific; they have important implications for development, construction projects, land-use, hazard mapping, and resource management in the Himalaya and Tibet.

Although the Himalaya-Tibetan region is fundamentally the product of a compressional (crustal shortening) tectonic regime, it has long been known that there are east-west extending grabens in Tibet, suggesting the gravitational collapse of the plateau. Over the past decade, discovery of a basement-cover detachment – the so-called South Tibetan Detachment⁶ – in the Himalaya has drawn a widespread interest among geologists. The South Tibetan Detachment essentially separates the Paleozoic sedimentary sequence of the Tethys Himalaya (on its hanging wall to the north) from the high grade metamorphic and granitic rocks of the Higher Himalaya (on its footwall to the south). More detailed studies have also mapped extensional structures in other geological zones of the Himalaya; for example, S-C fabrics in the Higher Himalayan metamorphic zone, and normal

faults in the foothills of the Himalaya. Interestingly, unlike the east-west spreading grabens of Tibet, the Himalayan extensional structures are parallel to the general east-west strike of the mountains, demonstrating that compression and extension have occurred in the same north-south direction. Available geochronological data also indicate that these two events may be temporally linked to each other. The existence of these two contrasting tectonic regimes in a single orogenic system (which is also, geologically speaking, quite young and still active) provides crucial clues to understanding how tectonic processes deform rocks and develop highlands on the earth as well as put physical caps on their development. Kip Hodges of Massachusetts Institute of Technology remarked that it is no wonder that the highest fault on earth (on top of Mount Everest) is a normal fault. The third special session (on May 1) discussed Himalaya-Tibetan examples of 'Extensional tectonics in a compressional orogenic system'. This area of Himalayan research is expected to attract more attention in the coming years. Especially important will be close examinations of (i) absolute time relations between the activity of the South Tibetan Detachment marking the northern boundary of the Higher Himalayan metamorphic zone and the Main Central Thrust marking its southern boundary; (ii) the relations of Himalayan granites produced by crustal anatexis during the Tertiary both to compressional (hence crustal thickening) tectonics and extensional (hence decompressional melting) tectonics; and (iii) similarities and variations in tectonic style and timing of extensional faults along the strike of the Himalaya.

The afternoon sessions of the workshop covered regional topics. On April 29, two parallel sessions were held on 'Western Himalaya/Karakoram' and 'Sub-Himalaya (Foreland Sediments)'. On April 30, 'The Main Central Thrust Zone' as well as the Poster Session were covered. Finally on May 1, two other parallel sessions were held on 'The Higher Himalayan Crystalline Terrain' and 'Tibet and Trans-Himalaya'. Holding parallel sessions usually has the downside of splitting participants, which may not be welcome by the participants wishing to hear all the lectures. Nevertheless, it was not possible time-wise for the organizers to fit all of the presentations in single sessions

in a three-day workshop. Especially considering the view that in workshops (unlike conferences) more time should be given for questions and discussion. Indeed a novel aspect of the 11th H-K-T Workshop (differing from the usual 15-minute conference presentations) was that each oral presentation was 20 minutes long; furthermore, an open discussion (coordinated by two leaders) for one hour was held at the end of each session. This allowed for more questions, comments, and debates on the topics covered in each session.

A total of 101 presentations were made at the workshop: 71 oral and 30 posters. Geographic distribution of the presentations is shown in Figure 2. It can be seen that 49% of the presentations were on the western Himalaya (Pakistan and India), and that relatively much less research is conducted on the eastern parts of the Himalaya and on the Karakoram-Pamir-Hindu Kush mountains.

It is also informative to consider the distribution of the presentations in terms of the geological divisions of the Himalaya. The Himalaya is divided into five longitudinal zones, separated from each other by major faults⁷. These zones are as follows from north to south: (i) the Trans-Himalaya and the Indus-Tsangpo Suture Zone (the initial plate boundary between India and Asia); (ii) the Tethys (or Tibetan) Himalaya; (iii) the Higher (Greater) Himalaya; (iv) the Lesser (Lower) Himalaya; and (v) the Sub-Himalaya (Outer Himalaya or the Siwalik hills). Figure 3 shows the distribution of the presentations at the workshop according to geological divisions. 33% of the papers were on the Higher Himalayan metamorphic and granitic rocks (i.e. 'hard rocks') towards understanding such processes as metamorphism, crustal anatexis and emplacement of granites, processes of uplift and denudation of deep-seated rocks, timing of major faults and tectonic events in the Higher Himalaya. If the submitted abstracts is taken as a rough measure of research done in the Himalaya (this is a big IF, but the same inference can also be made from considering the subject-matter of Himalayan papers published in general geology journals), it is inferred that relatively less research is conducted in the Tethys Himalaya and the Lesser Himalaya. This is unfortunate because these two sedimentary zones provide valuable information on the Proterozoic, Paleozoic and Mesozoic events.

Only one paper on palaeontology (on the trilobites of the Zaskar region) was presented at the workshop. Much more research in Himalayan stratigraphy and palaeontology is required. The Tethys Himalaya has exposed marine sedimentary formations spanning in stratigraphic time from the trilobites of Cambrian seas until the Great Dying of Cretaceous ammonites. There are also Cenozoic sedimentary formations and fossils in the Himalaya, especially the mammalian fossils in the Siwalik Group, which provide valuable opportunities for examining the evolution of life and environment in the geological past.

Similarly more attention needs to be paid to the Lesser Himalaya. A major problem with this zone has traditionally been the lack of fossils to work out its stratigraphy and relative displacement of rock formations. Perhaps, this is a wrong expectation any more. Applications of high-resolution geochronological and geochemical techniques in conjunction with detailed field mapping in the Lesser Himalaya provide important clues to un-

Figure 2. Presentations (both oral and poster) at the 11th Himalaya-Karakoram-Tibet Workshop according to geographic regions of research (Tibet is here considered as a geopolitical region).

Figure 3. Presentations (both oral and poster) at the 11th Himalaya-Karakoram-Tibet Workshop according to the geological divisions (Tibetan Plateau is here considered as a geological zone to the north of Trans-Himalaya).

derstanding the Precambrian history of the earth. Moreover, the Lesser Himalaya is the most populous zone of the Himalaya, containing forests, agricultural lands, human settlements, infrastructures, etc. Research in such fields as geomorphology and neotectonics of the Lesser Himalaya would be important in terms of understanding the mountain-human interactions.

Selected, refereed papers resulting from the workshop will be edited by the organizers and published as a volume of the *Geological Society of America Special Paper*, and also possibly in a special volume of the journal *Tectonophysics*. Financial support for the Workshop came partly from registration fees and partly from a grant from the Continental Dynamics Program of the US National Science Foundation (NSF). The NSF grant mainly supported travel funds (some partial support and some full funds) for 24 researchers from the Himalayan countries (China, India, Nepal, and Pakistan) and students from Europe. The Indian participants at the workshop were from the

Wadia Institute of Himalayan Geology (Dehra Dun) and University of Roorkee. Overall, 28 of the participants were originally from the Himalayan countries (including those residing in the US or Europe). Indeed, one of the successes of the workshop was that it could provide financial support for native researchers in the Himalaya to attend this international meeting. (Nearly 100 applications were received for travel award; it was not financially possible for the committee on travel awards to respond positively to all of these requests.) Participation of researchers from the Himalayan countries is important for the H-K-T Workshops; however, not all organizers have been or will be able to obtain the necessary funds (especially in view of shrinking government budget for science in recent years). One solution is to hold the H-K-T Workshops frequently in the Himalayan countries (so far, only one of the workshops has been held in the Himalayan region, namely the Kathmandu Workshop in 1994). This solution was suggested in Flagstaff during the planning session for

the 1997 H-K-T Workshop, and deserves more attention.

The 12th H-K-T Workshop will be held in Rome (Italy) in April 1997 on the occasion of the 100th anniversary of birth of Ardito Desio, a geologist who carried out pioneering research in the Karakoram mountains.

Chaos – A new paradigm for comprehending nature

The earliest study of what is today known as *deterministic chaos* dates back to the paper entitled 'Deterministic Nonperiodic Flow' by E. N. Lorenz¹ in 1963. However the concepts of chaos took roots only in the seventies. By the eighties there was an exponential growth in the numbers of research articles and books. Journals devoted entirely to this dynamic new concept were started, and the number keeps increasing – especially if one considers the related areas of fractals and complexity.

A four-day Workshop on Complex Systems (chaos) was organized under the auspices of CSIR Technical Advisory Board (Physical, Environmental & Earth Sciences), hosted by C-MMACS, at C-MMACS/NAL from June 26 to 29, 1996. The motivation for holding this Workshop stemmed from the view that it would be desirable to empower CSIR scientists with a working knowledge and hands-on experience in this fascinating, new, dynamic area of physics so that they may make creative applications of

these paradigms to new problems in their respective fields. Interested scientists and students from outside CSIR were also included among the participants to ensure benefits on a wider scale. The participants had a background in diverse areas of physics, biology, engineering, mathematics, computer science, etc.

Deterministic chaos is a nonlinear phenomenon and is easily understood by studying the behaviour of the simple one-dimensional nonlinear map², the so-called logistic map, $x_{n+1} = \mu x_n(1 - x_n)$. This is so simple that one can programme it on a hand-held calculator without much trouble. A physical understanding of this equation can be gained by considering the variable x_n to represent the normalized population of some organism in the n th generation, x_{n+1} becoming the population in the next generation. The model is discrete in time and assumes that the size of the present population depends only on the size in the previous generation (some insect species do approximate such simple dynamics). The first factor on the

right hand side, μx_n , is the growth term and would lead to a runaway exponential increase but for the inclusion of the second factor. The latter, μx_n^2 , represents the decay term and the limit to growth such as, for example, controlled by a finite amount of food supply. Here, we treat x_n as a normalized variable (a proportion of some maximal population) and consider values $0 < x_n < 1$. The model exhibits a range of dynamical behaviours for different values of the parameter, μ . Figure 1 shows a sequence of values of x_n , with $n = 1, 2, 3, \dots$, namely an orbit of the system, for $\mu = 4$, and a similar behaviour is obtained regardless of any specific initial condition x_0 . There is no regularity in the sequence: it looks quite random in character and is, in fact, quite unpredictable. The unpredictability is evident when one starts off with two initial conditions which are very slightly different from each other. After just a few iterations, the two sequences bear no resemblance whatsoever, and can differ from each other by arbitrary amounts within

the general confinement. All the sequences are constrained to lie between 0 and 1, so the difference in absolute terms may not be large, but locally, nearby orbits diverge from each other at *exponential* rates. We have a situation where although the equation is deterministic, the outcome is neither regular nor predictable in the long run. This is characteristic of deterministic chaos.

In the early part of this century, a major paradigm shift occurred with the discovery of quantum theory, which introduced us to the uncertainty principle: that both of a pair of complementary dynamical variables (observables), such as position and momentum, cannot be measured with arbitrary accuracy simultaneously. This led to the formulation of the mathematical apparatus of the theory in terms of probabilities. However, the probability functions themselves were evolved using deterministic equations in the theory. The philosophical ramification of all this has been, and continues to be, debated extensively.

In the past decade, *chaos theory* has again confronted us with the question of limits to predictability³: it says that, as long as the equations of evolution are nonlinear, even if deterministic, any imprecision in initial measurements, can, during subsequent evolution, get magnified exponentially fast, so that no predictions can be made with sufficient accuracy in the long run. This is a statement with far reaching implications. Almost all systems are nonlinear in nature: linearity is most often a convenient approximation. However, until recently, most developments in science and technology have been based on this approximation. This is understandable because linear theory is analytically tractable whereas nonlinearity, in general, is not. It is only with the advent of computers that it has become possible to tackle nonlinearity directly, using numerical tools.

Quite apart from the philosophical implications, beautiful results and techniques have been spawned by the chaos theory⁴. The hallmark of chaos, namely the sensitivity to initial conditions or the exponential divergence of nearby trajectories can be quantified by the rate of divergence, which is termed the Lyapunov exponent. A positive exponent implies exponential separation of trajectories or chaos. There are as many exponents as

there are phase space dimensions and, while divergence occurs in some directions, contraction can occur along other directions. For conservative systems, the net expansion is zero whereas in dissipative systems volumes contract (we deal only with the latter case here). Thus, even though nearby trajectories diverge, globally all trajectories remain confined to some subset of the phase space. This is achieved by a process of folding back of the trajectories at the boundaries. This process of local divergence and global confinement through 'stretching and folding' is typical of systems where the motion is chaotic (a good visual mnemonic of such a process is the kneading of dough by a baker). Coupled with the contraction of phase space volumes, what results in phase space is an *attractor*, namely the orbit to which progression from any initial conditions eventually converge. When the motion is chaotic, the attractor often has a fractal geometry, and is termed *strange*. Systems can have different strange attractors and fractal (non-integer) dimensions have to be used to characterize them. Nonlinear dissipative systems can have simple attractors as well, such as fixed points (steady states) or limit cycles.

A remarkable result from chaos theory has been the discovery of universal routes to chaos. As a control parameter (as for

example μ in the map above) is varied, one observes qualitative changes in the dynamical behaviour and the phase space dynamics switches between the different attractors in a universal manner. Three well-defined universal routes to chaos have been documented in various experiments: the Feigenbaum scenario or the period-doubling route to chaos, intermittency and the Ruelle-Takens or strange attractor scenario. The period doubling route is characterized by a set of universal numbers, which relate to the way in which aperiodic behaviour is approached. As the parameter is varied, one observes period doubling, i.e. from a steady state to a periodic motion with period (say) T , to $2T$, to $4T$, $8T$, ..., $2^n T$ and thus on to an aperiodic or chaotic behaviour. The parameter windows in which successive periods exist keep getting smaller and the ratio of two such successive window lengths approaches a universal number, the so-called Feigenbaum constant, which has the numerical value 4.669.... In essence, what happens is that, as the parameter varies, one limit cycle becomes unstable and a new limit cycle of twice the period is stabilized. Ultimately no cycle is stable but all exist, albeit as unstable ones. In other words, chaos can be considered as a closure of unstable periodic orbits. It is possible then to visualize chaotic dynamics as one in

Figure 1. Sensitivity to initial conditions, hallmark of *deterministic chaos*: two sequences of iterates of logistic map differing only in the twelfth decimal place in the initial conditions.

which the phase space orbit gets kicked from one unstable orbit to another and keeps wandering in the skeleton formed by the unstable periodic orbits, unable to settle down on any of them.

Dynamical chaos can be exploited. The knowledge that there are unstable periodic orbits within chaotic regions has been used to devise beautiful control algorithms, where a nonlinear dynamical system can be made to have a desired dynamical behaviour corresponding to a particular periodic orbit. Since the system is extremely sensitive, small parameter changes are enough to manipulate the dynamics and it is possible to design a series of such small parametric perturbations to keep the system around a periodic orbit of interest. This possibility vests chaos with a desirable feature where it provides for versatile design options. For, one can thus control, simply by tuning parameters involving very small changes, and switch the system from one periodic behaviour to another, and no major design modifications are called for!

Experimental data from biological systems appear to suggest that nature has indeed incorporated some of these aspects of chaos into its engineering designs. EEG data from individuals in different stages of consciousness indicate that wakefulness is characterized by chaotic dynamics whereas different stages of sleep are marked by different periodic oscillations. Furthermore, pathological conditions in brain, for example epileptic states, are marked by periodic behaviour.

One of the most important features of deterministic chaos is that it can arise in systems of low dimensionality. In discrete systems, one-dimensional maps (if non-invertible; else two-dimensional) exhibit chaos and, in continuous systems, three variables, coupled ordinary differential equations are sufficient (nonlinearity being, of course, a prerequisite). Quite obviously, the Newtonian world view – Laplacian determinism – which attributed randomness to high dimensional, complex systems that are 'difficult' to be modelled in complete detail seems unnecessary in hindsight and recent attempts to model complex systems such as the weather or climate, biological systems like the heart or brain, etc. using low-dimensional deterministic nonlinear equations, have attained some measure of success. Simultaneously, data from such systems when analysed to ascertain

the actual effective dimensionality of those systems reveal them to be indeed low-dimensional in very many cases.

The study of complex phenomena is not restricted to the dynamical regime. A significant development in the study of complex systems was the introduction of the concept of self-organized criticality by Bak, Tang and Wiesenfeld⁵ (BTW) in 1987. Critical points are familiar from the study of phase transitions and they are approached by the tuning of an external parameter such as, for example, temperature in the case of water-to-ice transition. However, in self-organized criticality, there is no need to tune any parameter and the system is constantly maintained in the critical state by processes of self-organization: these are far-from-equilibrium systems⁶. The paradigmatic model that BTW studied is that of sandpiles: sand is added a grain at a time, and the slope of the pile keeps fluctuating between a minimum and a maximum value within a small range. In the steady state, the system is marginally stable and avalanches of all sizes occur as the slope keeps fluctuating. The model which is a simplified description of systems with extended spatial degrees of freedom, has generated considerable interest. An important natural phenomenon that is seen to correspond to this class of systems is that of earthquakes with their associated stick-slip dynamics.

Sandpiles are simple, paradigmatic models for complex phenomena, but, at the same time, they themselves are very complex systems from another perspective. In fact, they have been referred to as a 'new' state of matter, the *granular state*, which is intermediate between solids and liquids, having properties such as dilatancy, hysteresis, etc. A unique characteristic of sand is to sustain the evolution of bridges and arches which, unlike in liquids and gases, do not get thermally averaged away and play a significant role in stasis and dynamics. For example, due to these local formations, the stress distribution at the bottom of a sandpile is quite complicated. Again, the packing configurations are significantly affected by the presence of such formations.

The problem of turbulence is one that continues to challenge physicists. In the light of new developments, some of which have been described above, this is now described as 'fully developed chaos'. New techniques of analysis from chaos theory

have been applied to turbulence data to gain some new perspectives.

Among the new techniques that have come up, a very useful one is that of phase space reconstruction. Quite often, in experimental situations, only one, or at most a few, of the variables involved in the dynamics can be measured. In the absence of a knowledge of the complete set of phase space variables, it is still possible to construct a pseudo-phase space which is topologically equivalent to the (unknown) original. The set of new coordinates for such a phase space is constructed from the available one by using time-shifted, lagged values: if $v(1), v(2), \dots$ are the measurements of a variable v at time intervals $1, 2, \dots$, the time series for the second coordinate can be taken as $v(1 + \tau), v(2 + \tau), \dots$, with τ , an integer multiple of sampling time, chosen in an appropriate manner so as to avoid redundancy. The phase space thus reconstructed can be used to estimate dynamically relevant quantities like Lyapunov exponents, fractal dimensions, unstable periodic orbits, etc.

The widespread availability of powerful electronic computers has played a major role in many of these developments by making the simulation of complex systems tractable. Many studies of complex behaviour can be carried out with simple models that capture the essential features. Cellular automata – where space, time and all variables are taken to have only integer values – have been extensively used to model a variety of such systems. Coupled-map lattice models – where space and time are discrete – also provide a numerical methodology capable of displaying rich phenomena.

It is this fascinating, frontier area of physics that was the subject matter of the workshop. The workshop began with a keynote lecture by R. Ramaswamy (JNU, Delhi). Dissipative systems were reviewed in two lectures by V. Balakrishnan, (IIT-Madras). Neelima Gupte (IIT-Madras) gave three talks. In the first one, she introduced the basic concepts of fractals, the fascinating field of new geometry, which appears to describe natural objects such as trees, clouds, coastlines, mountain profiles, etc., all of which have non-integer dimensions. Her second lecture dealt with the control of chaos and the third was on synchronization. The latter has important applications, particularly with respect to encryption of

messages (of importance in defence) where the messages are masked by synchronizing with chaotic waveforms.

T. R. Krishna Mohan (C-MMACS, Bangalore) explained the procedures for reconstruction of a phase space from single variable time series and the estimation of correlation dimension (Grassberger-Procaccia algorithm⁷) and Lyapunov exponents from the phase space dynamics. Pradhan (NIMHANS, Bangalore) discussed and explained the problems associated with ascertaining whether a time series originates from nonlinear, deterministic evolution or from a linear, stochastic process which can give rise to coloured noise having similar spectral properties. Prabhakar Vaidya (Washington State University, now visiting C-MMACS) gave a talk on methods that can be used for unambiguously confirming the presence of a nonlinear, deterministic process in time series; the methods he spoke on (trans-spectral coherence) are related to higher order spectral methods and can also be used in connection with premonition of chaos, i.e. to identify possible transition to chaotic states.

Deepak Dhar (TIFR, Mumbai) gave two lectures on self-organized criticality and sandpile models; he showed the relationship of abelian sandpile models to other related models such as Potts model, Voter model, Takayasu aggregation model and river networks.

Anita Mehta (S. N. Bose Institute for Basic Sciences, Calcutta) spoke on the

complexity of granular materials, namely sand, and the relevance of ideas such as self-organized criticality to the physics of actual sandpiles. Sudeshna Sinha (Indian Institute of Astrophysics, Bangalore) discussed the general strategies of modelling spatio-temporal phenomena by coupled-map lattice models.

Three afternoon sessions were devoted to experiments. A variety of PC-based computer programs were made available to participants in order to help them understand the various concepts covered during the lectures, and to enable them further explore different aspects of chaotic dynamics and fractal geometry through numerical experiments. There were also experiments using electronic circuits to show the period doubling route to chaos, as well as strange attractors. A practical realization of the phenomenon of chaotic synchronization using two circuits was shown, and the ideas of secure communication using chaotic masking was demonstrated by Manu and Kapilanjani Krishan of Khalsa College, New Delhi.

Three evening colloquium talks marked the conclusion of the workshop activities on each day. Anita Mehta gave a general overview of the physics of sand, of the physics of granular state, in her colloquium talk, 'Probing Sand'. Rahul Pandit (IISc, Bangalore) talked on homogeneous, isotropic turbulence with emphasis on the scaling of velocity structure functions, on the multiscaling and self-similarity aspects. In another, R. Narasimha (IISc and

JNCASR, Bangalore) talked on aspects of clouds as complex systems with focus on understanding of entrainment process in tall cumulus clouds where horizontal diffusion is practically nil and vertical diffusion is practically infinite! He described experiments being carried out at IISc (with Prabhu and Bhat) to study the mechanism of this strange behaviour. The large-scale vortical structures in the flow 'engulf' ambient fluid from the surroundings in the first process of entrainment, followed by 'mingling' of the engulfed fluid into the core flow and, finally, it is 'mixed' in at the molecular level. The experiments are designed to study the modifications brought about by local heating which takes place, for example, by the release of latent heat during condensation, in clouds.

OPINION

Monsoon: A bioclimatologist's point of view

V. M. Meher-Homji

A plant geographer's main concern with the climate is to seek correlations with the vegetation. Precipitation, temperature and evapotranspiration have been commonly used. Lesser known factors like the régime (season of occurrence of rains) have been developed here for a better understanding of eco-diversity. Briefly discussed are the different origins of rainfall in India, the variability in the climatic factors and the transition from the Mediterranean régime to the west of the Indian sub-continent to the tropical monsoon type in the peninsula, across the Thar desert. A critical review is presented on palaeopalynological studies that tried to make out monsoon fluctuations during the Holocene. Deforestation may affect the local rainfall pattern without there being a change in the intensity of monsoon as a planetary phenomenon.

The monsoon, the very pulse of the Indian economy, is a word of Arabic origin

'mausim' meaning season. The term implies the seasonal reversal of the wind

systems on which depended the marine navigation for the purpose of trade. Since

the south-west winds are accompanied by rains, the layman tends to equate the monsoon with rainfall.

Different meteorological origins of rainfall

In a country like India, rainfall could be of different origin in meteorological sense. The south-west monsoon, the major source of moisture in the Indian peninsula, prevails from May–June to September–October. This system very much depends on the sea surface temperature and pressure. El Nino years witness reversal of normal conditions and consequently the monsoon fails in India.

There are two branches of the SW monsoon, the Bay of Bengal branch arriving earlier than the Arabian sea branch. Calcutta receives rain in the last week of May but Bombay only towards the second week of June. After September with the shift in the heat belt from Rajasthan–Punjab to the equator, the winds change direction; from mid-October to December dominate the north-east winds. The rains received in the Coromandel–Circar coastal region during this season are assigned to the NE monsoon. Earlier, the geographers believed that the winds from the north blowing over the Bay of Bengal picked up moisture and provided rains to coastal Tamil Nadu and Andhra Pradesh during the cooler season. Hence the term NE monsoon or retreating monsoon. However, when the winds are blowing from the north-east, the weather remains bright and clear. These are the depressions and cyclones formed during this season in the Bay which bring rains on the east coast. As the frequency of depression formation is highly variable, the rainfall also fluctuates a good deal, from 600 mm to 2000 mm at Madras.

Rainfall may be of orographic origin in the hills. The principle is that an air-mass striking a vertical obstacle like a mountain tends to rise. Finally, the rainfall may be of convectional origin. Due to excessive heating of certain pockets of land, especially in the pre-monsoon months, rising currents of air are set into motion taking the cloud moisture to considerable heights. Perhaps, it is the convectional type of rainfall that is most affected by the forest cover. Historical records reveal that the Chota Nagpur plateau of Bihar used to receive regular afternoon showers in April–May which

favoured tea gardens but as probable result of massive deforestation carried out towards the turn of the century, this instability rain disappeared and it is no longer possible to grow tea in the area. Yet another example is that of Udhagamandalam (Ooty) which had 375 rainy days for the 5-year period 1870–1874, excluding the SW monsoon months June to August. For the 5-year period a century later, applying the same criteria, the number of rainy days has declined to 270 (ref. 1). It would be an interesting exercise to work out the contribution of these different categories of rainfall to the annual total.

Régimes of rainfall

Though India is a tropical country, the season(s) of occurrence of rains vary from one part to the other. Mangalore (Figure 1) represents the typical tropical *régime* with rains beginning in late May and terminating after October, the peak being in July. Thus the rainfall curve maintains a perfect symmetry in the course of the year. Coming to the east coast of Tamil Nadu, at Tirunelveli (Figure 2), the symmetry of the curve is lost as the bulk of rains are received in October–November from the so-called NE monsoon. The rainfall is not only low but also erratic during the SW monsoon season over the Coromandel coast. In fact the character of rainfall in June, July, August at Madras and Pondicherry suggests that these are convectional showers (thunderstorms); over 85 per cent of rains occur between sunset and sunrise in short spells mostly accompanied by thunder and lightening.

Mysore (Figure 3) also experiences little rains during the SW monsoon; the *régime* is characterized by two peaks, one in April (due to convection) and the other in October (depressions and convection). The two peaks are reminiscent of the equatorial *régime* of the stations close to the equator like Colombo. Udhagamandalam (Figure 4) has a three-peak *régime*: July (SW monsoon), besides April and October. These few samples illustrate the range of *régime* in India^{2,3}.

Régimes and vegetation

Realizing that the vegetation is determined by several variables of climatic factors, Köppen⁴ used the data of precipitation

together with the temperature to establish the boundaries between the arid, semi-arid and humid climates and the corresponding vegetation. Given that the precipitation

Figure 1. Rainfall *régime* at Mangalore (alt = 22 m). Δ = Rainfall curve; \circ = Octile values; P = Rainfall; RD = Number of rainy days; DS = Length of dry period in months.

is more effective if it occurs during winter than in summer, he assigned different weightage to the areas of summer rainfall and winter rainfall.

We wish to highlight the role of *régime* factor, i.e. of the season of occurrence of rains with reference to some noteworthy examples of vegetation in India. The forest map (Figure 5) shows the dominance of sal (*Shorea robusta*) in the eastern half of the peninsula and that of teak (*Tectona grandis*) in the western half. In terms of rainfall quantum, temperature, length of the dry period there is not much difference in the ranges of these factors. What is important is the timely arrival of rains when the viable seeds of sal are available. The seeds have a short

period of viability of about ten days. If the rains are not in time, the germination fails. The rains which set in earlier in the eastern part of the peninsula favour the sal germination. As rains are delayed in the western counterpart, sal gradually disappears westwards and the dominance is taken by teak. In coastal plains of Tamil Nadu prevails a very unique vegetation type termed as the *tropical dry evergreen forest*. Occurring in the physiognomic form of scrub jungle, it is deprived of the typical species of the deciduous forest like teak, sal, rosewood and many more. The distribution of this type coincides with the zone experiencing the dissymmetric type of rainfall *régime* illustrated in Figure 2.

The economically valuable red sanders tree (*Pterocarpus santalinus*) is confined to the Cuddapah basin and the Nallamalai Hills in Andhra Pradesh. Its endemic occurrence corresponds to the zone where the transition is taking place from the dissymmetric *régime* of Nellore on the Coromandel coast to the typical tropical *régime* of Kurnool on the Deccan plateau (Figure 6) (ref. 5). These few instances bring out the significance of rainfall

régime factor in bioclimatology, a factor ignored both in geography and forestry.

Variability of monsoon

The inter-yearly variability in the wake of the vagaries of monsoon distorts the image of the climate based on averages. The variations in the annual quantum of rainfall are too familiar to merit further discussion. The consequent fluctuations in the length of the dry period though significant in plant geography have been almost overlooked. At Kodaikanal, the majority of individual years experience a dry period of 1 to 4 months, yet on the basis of averages, the dry season does not come out as the dry spells occur in different months in different years. New Delhi, with an average dry period lasting for 9 months, has the range of dryness of 7 to 11 months.

In other cases, the variations involve

Figure 2. Rainfall *régime* at Tirunelveli (alt = 42 m). Δ = Rainfall curve; \circ = Octile values; P = Rainfall; RD = Number of rainy days; DS = Length of dry period in months.

Figure 3. Rainfall *régime* at Mysore (alt = 767 m). Δ = Rainfall curve; \circ = Octile values; P = Rainfall; RD = Number of rainy days; DS = Length of dry period in months.

Figure 4. Rainfall *régime* at Udhagamandalam (alt = 2249 m). Δ = Rainfall curve; \circ = Octile values; P = Rainfall; RD = Number of rainy days; DS = Length of dry period in months.

the *régime*. Some stations in the northern and north-western parts of the sub-continent present the average *régime* of Mediterranean type with winter-spring rains brought on by the western disturbances, and summer dryness. However, the *régime* tends to vary from year to year as exemplified by the climate dia-

grams of Peshawar (Figure 7). The interplay between the two rain-bearing meteorological phenomena, — western disturbances and summer monsoon, in the Indo-Pakistan arid zone results in a series of *régimes* shown in Figure 7. It is in this desertic tract of the Thar and adjoining regions that the transition takes place from

the Mediterranean *régime* of countries like Iran and Afghanistan to the tropical monsoon *régime* of peninsular India.

Palynology and the intensity of monsoon during the Holocene

Palynological data have been used to

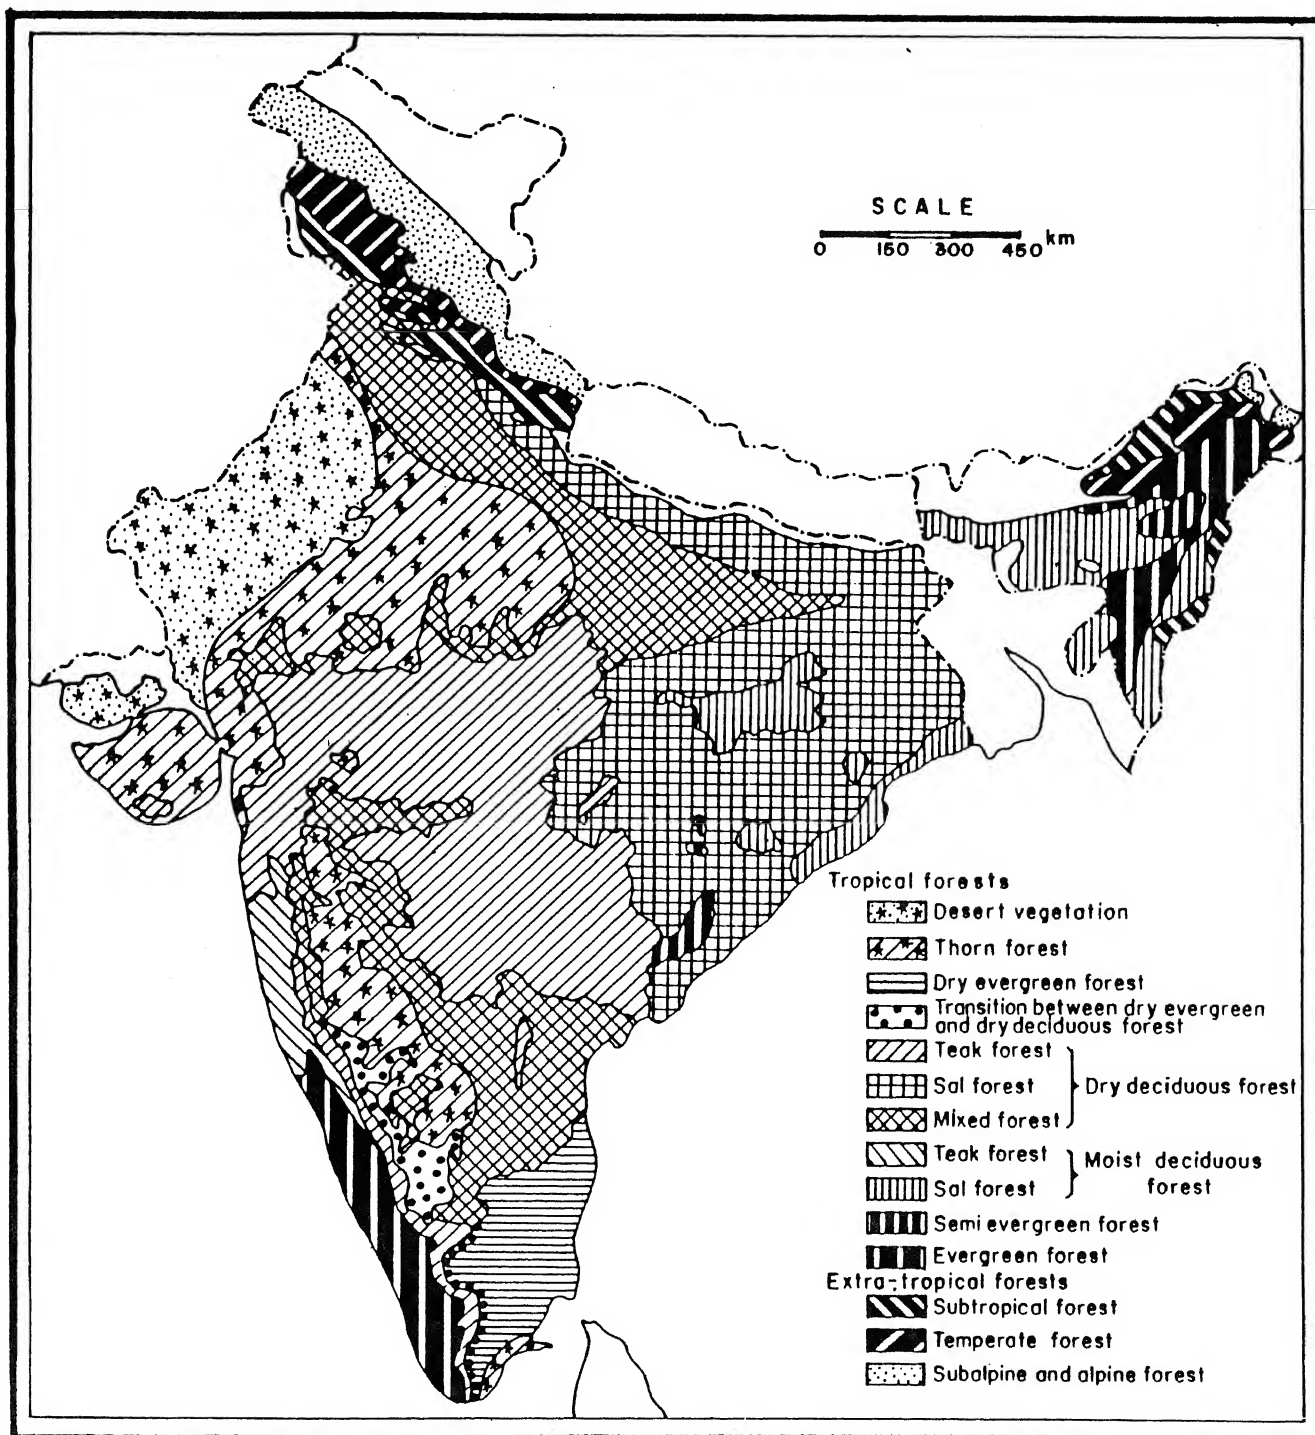

Figure 5. Forest types of India.

Figure 6. Climate diagrams and area of the red sanders.

decipher the strength of monsoon, weak or strong, within the last 10,000 years. Gurdip Singh *et al.*⁶, based on the analysis of pollen grains of sediments of lakes in

Rajasthan suggested alternation of several relatively humid phases with drier ones during the Holocene. However, the species selected as markers of stronger mon-

soon activity are unfortunately not very fidel indicators of humid conditions⁷⁻⁹. If the rainfall had taken a distinct upward trend, why do the pollen of deciduous forest species of the Aravallis find no representation in the profile of the Sambhar lake?

Caratini *et al.*¹⁰ analysing two marine cores collected from the inner shelf off Karwar opposite the mouth of the Kalinadi for their pollen content observed a change in the vegetation pattern beginning around 3200 years BP, getting more pronounced a millennium later and stabilizing thereafter. A marked decline in the pollen of the evergreen, deciduous and mangrove forest species in the favour of grassland species was taken as an indication of onset of a less humid phase linked to a weaker monsoon. However, the anthropogenic interference cannot be ruled out altogether in bringing about the vegetation change. Man's activity started with iron implements around 1000 BC or even earlier with slash and burn agriculture^{11,12}. Grasslands are essentially the result of passage of fire at low and middle elevation. Paddy cultivation in the estuaries was probably the reason for the decrease of mangroves¹¹.

The decline in rainfall need not necessarily imply a weakening of monsoon activity; large scale deforestation may affect the microclimate and local rainfall. The link between forests and rainfall has been a controversial issue and a debated topic. Gadgil and Prasad¹³ have stressed the use of realistic models capable of simulating the various effects of deforestation such as changes in albedo and soil moisture. Their computer experiments have shown that model simulated climates are influenced by land-surface boundary conditions. The areas most likely to undergo desertification in view of deforestation and the attendant biogeographic feedbacks are those in the vicinity of arid zones. The increasing marine influence noted by Caratini *et al.*¹⁰ through proliferation of marine organisms like copepods, dinoflagellates, foraminifera and organic carbon of marine origin around 2200 years BP was likely due to a decrease in the flow of fresh water, in turn probably linked to massive deforestation.

In conclusion, the archaeological evidence of increasing human influence on the vegetation cover and the role of forests on the local climate deserve consideration

Peroxidase activity in relation to *in vitro* rhizogenesis and precocious flowering in *Bambusa arundinacea*

Bambusa arundinacea, a multipurpose, monocarpic, woody perennial bamboo, exhibits gregarious flowering once after a prolonged intermast period of 30–45 years¹. Incidentally, we noticed *in vitro* flowering in one out of ten seedling lines of *B. arundinacea*. The physiological basis of such flowering in bamboos has not been investigated. However, Gaspar, while studying variation in peroxidase activity in relation to *in vitro* rhizogenesis in several plant species, proposed that rhizogenesis and flowering are two antagonistic phenomena, preceding respective minimum and maximum levels of peroxidase activity^{2,3}. Therefore, we sequentially followed peroxidase activity *vis-à-vis* the *in vitro* rhizogenesis and precocious flowering in *B. arundinacea*.

Ten subculture-cycle-old clonal explants from the seedling line of *B. arundinacea*, which exhibited *in vitro* precocious flowering during the 6–7 subculture cycle, were chosen for the present study. The clonal explants were maintained on 0.7% agarified and 3% sucrose enriched MS medium⁴ supplemented with 2 mg l⁻¹ BA for shoot multiplication and 3 mg l⁻¹ NAA for rooting of multiplied

shoots. pH of the medium was adjusted to 5.8 before autoclaving, and the cultures were kept at 25 ± 2°C under 16 h photoperiod from white fluorescent tubes. Root and flower primordia were visible within 10 days and after 45 days of inoculation on rooting medium respectively. The sampling for peroxidase activity⁵ and protein content⁶ was done daily for an initial ten days and on every third day after eighteenth day onwards until the appearance of flower primordia, taking three samples each of 100 mg shoots from cultures maintained on rooting medium. The data presented here represent mean of three experiments, using independent sets of proliferated shoots, and have been subjected to statistical analysis, employing Student's *t* test at *p* = 0.05 level of significance for comparing mean values of peroxidase activity recorded at various days after inoculation.

The peroxidase activity of *in vitro* proliferated shoots transferred on rooting medium exhibited a definite pattern, attaining significant minimum values at 7 days and 42 days; but the *in vitro* root and flower primordia were visible at 10 days and 45 days respectively after inoculation

(Figure 1). In fact, *de novo* organogenesis is a complex phenomenon, involving a cascade of cytological events, e.g. cell division, elongation and maturation (differentiation). The observed depression in peroxidase activity prior to appearance of root or flower primordia presumably indicates initial events such as cell division and elongation, whereas its subsequent elevation until formation of roots and flowers (Figures 1 and 2) seems to be associated with lignification of differentiating cells, i.e. cell maturation. The role of peroxidase in lignification of cells is well established as it catalyses the oxidation of cinnamyl alcohols into lignin precursors⁷. There is no report in the

Figure 1. Peroxidase activity [A470 min⁻¹ (mg protein)⁻¹] in relation to *in vitro* rhizogenesis and precocious flowering in *Bambusa arundinacea* explants inoculated on rooting medium (MS + NAA). Arrow heads at 10 days and 45 days indicate the appearance of root and flower primordia respectively. Data represent mean ± SE of three experiments.

Figure 2. Plantlets of *Bambusa arundinacea* showing (a) adventitious roots (10-day-old), (b) precocious flowers with stamens (45-day-old).

literature, establishing a relationship between peroxidase activity and various stages of organogenesis. However, Rama Rao *et al.*⁵ have shown that the peroxidase activity remains minimum at fiber initiation and elongation and becomes maximum at fiber maturation in cotton.

Further, our observation that the formation of *in vitro* roots and flowers precedes the minimum level of peroxidase activity is in agreement with that on *in vitro* rhizogenesis in several plant species⁷ and cyclic bud formation in date palm⁸. However, the present data do not support Gaspar's assumption^{2,3}. It seems likely that the *de novo* organogenesis precedes a circumstantial minimum level of peroxidase activity.

In the present study, the multiple shoots of *B. arundinacea* exhibited the *in vitro* precocious flowering when they were maintained on rooting medium (MS medium + NAA) for a long period of 45 days. These results indirectly confirm those of Nadgauda *et al.*⁹, who reported the *in vitro* precocious flowering in this species on cytokinin-enriched multiplication medium. It may be possible that multiple shoots of the seedling line used in the present study possessed the genetic potential for precocious flowering which got expressed on accumulation of

sufficient cytokinin (BA) level due to undergoing several cycles on the multiplication medium. Therefore, the *in vitro* precocious flowering in bamboos as reported in the present study and elsewhere⁹⁻¹¹ seems to be independent of culture conditions (light, medium, temperature, etc.), and cytokinin (BA) probably helps only in expression of this potential.

Hence, we conclude that the low peroxidase activity reflects early events (e.g. cell division and elongation) in the sequence of *de novo* organogenesis rather than organ-specific differentiation of root or flower. Further, the *in vitro* precocious flowering in bamboos is probably genetically controlled, with cytokinin (BA) playing a complementary role in the process.

INDIAN ACADEMY OF SCIENCES

Discussion Meeting on Instability and Transition in Fluid Flows

22-25 November 1996 - Orange County, Coorg District, Karnataka

This discussion meeting is intended to get together Indian scientists active in the area to discuss current research as well as possible future directions, and to encourage formulation of any joint projects that might be of interest to them. Speakers at the meeting will include Indian scientists pursuing research in stability and transition as well as some visitors from abroad, including Dr Jitesh Gajjar (University of Manchester), Prof. Michael Gaster (Queen Mary & Westfield College, London) and Prof. K. R. Sreenivasan (Yale University). A small number of places in the meeting will be available for students, university faculty and other scientists either working in the area or seriously intending to do so. If you are interested in attending the meeting, please send a copy of your bio-data with a brief statement of interest to

Prof. Roddam Narasimha
Centre for Atmospheric Sciences
Indian Institute of Science
Bangalore 560 012

(Fax: 080-334 1683, e-mail: roddam@cas.iisc.ernet.in).

Participants will be required to be present in Bangalore before the evening of 21 November 1996 and will be brought back to Bangalore on the evening of 25 November. Arrangements for transport to and accommodation at the venue of the meeting will be taken care of by the Indian Academy of Sciences.

Gene therapy: Principles, practice, problems and prospects

P. N. Rangarajan* and G. Padmanaban*[†]

*Department of Biochemistry, Indian Institute of Science, Bangalore 560 012, India

[†]Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore 560 064, India

The remarkable advances made in recombinant DNA technology over the last two decades have paved way for the use of gene transfer to treat human diseases. Several protocols have been developed for the introduction and expression of genes in humans, but the clinical efficacy has not been conclusively demonstrated in any of them. The eventual success of gene therapy for genetic and acquired disorders depends on the development of better gene transfer vectors for sustained, long term expression of foreign genes as well as a better understanding of the pathophysiology of human diseases. It is heartening to note that some of the gene therapy protocols have found other applications such as the genetic immunization or DNA vaccines, which is being heralded as the third vaccine revolution. Gene therapy is yet to become a dream come true, but the light is seen at the end of the tunnel.

THE advent of recombinant DNA technology and the availability of a wide array of gene cloning techniques have had a dramatic impact on the conduct of research in biology and medicine. The molecular biological revolution has opened the floodgates for basic and applied research and researchers are using genes as double-edged weapons for both understanding basic cellular processes as well as biotechnological applications. Techniques such as polymerase chain reaction, non-radioactive nucleic acid probes, ribozymes, transgenics, gene knockouts, chromosome jumping and fluorescent *in situ* hybridization have revolutionized disease diagnosis and therapy. Genetic information in the form of expressed sequence tags (ESTs) and whole genome sequences are filling computer data banks faster than ever and never has gene cloning found more prominence in biology than it has now¹. Thanks to the brute force approach of positional cloning, it is now possible to identify a disease gene without any knowledge of its biochemical function. The difference between basic and applied research is disappearing fast and the results of basic research are finding immediate biotechnological applications. Gene cloning has enabled us to link DNA repair and cancer, transcription and xeroderma pigmentosum, cell cycle and malignancy and glycolysis and Huntington's disease. Thus, genes are the ultimate molecular switches that control various cellular processes and

abnormal gene expression can manifest in the form of specific genetic disorders and even compromise the ability of an individual to destroy invading pathogens and tumour cells. It is this overwhelming evidence in favour of genes and their critical role in maintaining physiological homeostasis that has strengthened the notion of using genes as therapeutic agents. The idea of delivering genes into humans to correct a disease phenotype remained a biologist's fantasy for a long time until the last decade, when it has been accepted as a scientifically viable proposition, recognized as an independent discipline and christened 'gene therapy'.

Principles and practice

The ultimate goal of human gene therapy is to replace a defective gene with a normal one via targeted insertion into the genome by homologous recombination. Such a strategy, referred to as gene replacement therapy, would not only permit physiological regulation of the transgene but also eliminate the possibility of insertional inactivation of other cellular genes, which happens during random integration of the foreign gene. However, the frequency of random integration versus site-specific integration is so overwhelmingly in favour of the former that gene replacement therapy continues to elude biologists. Recent studies with adeno-associated viral vectors have demonstrated that it is possible to deliver genes to a specific locus in human chromosome 19 and this is an improvement over random integration of genes². A major advantage of integrating foreign genes into the genome is that the expression is relatively stable and long-lasting and in case of dividing cells, the gene is acquired by the daughter cells as well. An alternative approach has been to avoid genome integration altogether and express genes transiently. However, in this case, the foreign DNA is more susceptible to nuclease degradation, and the gene expression is not as stable as seen in integrated genes. Transient vector systems are appropriate for therapies requiring short-term expression, such as in cancer therapy protocols but is not favoured for long-term correction of genetic defects. Overall, the current strategy for gene therapy largely centres around gene augmentation therapy, wherein the foreign gene

replaces the product of the defective or missing gene, but does not physically replace the defective gene itself. At present, two gene transfer strategies are in vogue: the *in vivo* approach, which involves introducing genes directly into the target organs of an individual whereas in the alternative *ex vivo* approach, cells are isolated for gene transfer *in vitro*, followed by transplantation of genetically modified cells back into the patients³.

All the genetic manipulations that can be performed in humans can be classified into four distinct categories: i) somatic gene therapy (correction of a genetic defect in the somatic cells of the body), ii) germ-line gene therapy (introduction of genes into the germ cells for the correction of the genetic defect in the offsprings), iii) enhancement genetic engineering (gene transfer for improvement of a specific trait, such as introducing a growth hormone gene to increase height), iv) eugenic genetic engineering (genes may be inserted to alter or improve complex traits such as intelligence and personality). While somatic gene therapy is now being attempted on human patients, germ-line gene therapy and enhancement genetic engineering are being carried out in laboratory and farm animals. Germ-line gene therapy is not

being attempted in humans for reasons that are as much ethical as technical and eugenic gene therapy is far beyond our technical capabilities and ethically questionable. In fact, the technical problems associated with somatic gene therapy in humans are so overwhelming, that unless we gain sufficient expertise in performing successfully gene transfer in the somatic cells, it may not be possible to carry out other genetic manipulations in humans⁴.

Somatic gene therapy was initially formulated for the treatment of monogenic defects, but now holds promise for a wide range of disorders including cancer, neurological disorders, heart disease and infectious diseases (Table 1). A variety of gene delivery strategies have been developed in the last decade for the treatment of human diseases and these can be grouped in two major categories: the viral and non-viral methods. Both these approaches are being pursued vigorously, although gene transfer through the viral vectors is more efficient than that by non-viral methods. Over several million years, viruses have evolved efficient mechanisms for the delivery of their own genomes into cells they infect and the strategy has been to replace these genes with those

Table 1. Genetic and acquired diseases amenable to gene therapy*

Disease	Therapeutic gene	Strategy	Vector	Target cells/tissue
Genetic disorders				
Cystic fibrosis	CFTR	<i>In vivo</i>	Adenovirus	Nasal epithelium
		<i>In vivo</i>	Cationic lipids	Nasal epithelium
Familial hypercholesterolaemia	LDL receptor	<i>Ex vivo</i>	Retrovirus	Hepatocytes
SCID	ADA	<i>Ex vivo</i>	Retrovirus	T cells, CD34 ⁺ stem cells
Haemophilia	Factor VIII/Factor IX	<i>In vivo</i>	Retrovirus	Hepatocytes, skin, muscle
		<i>Ex vivo</i>	Retrovirus	Hepatocytes, myoblasts
DMD	Dystrophin	<i>In vivo</i>	Retrovirus	Skeletal muscle
		<i>Ex vivo</i>	Retrovirus	Myoblasts
Acquired disorders				
Cancer	Interleukins, HSV-TK, TNF, HLA-B4, tumour suppressor genes	<i>Ex vivo</i>	Retrovirus	Tumour cells
		<i>In vivo</i>	Cationic lipids	Tumour cells
Cardiovascular disorders	tPA	<i>In vivo</i>	Cationic lipids	Endothelial cells
			Adenovirus	Endothelial cells
Alzheimer's disease	NGF	<i>Ex vivo</i>	Retrovirus	Fibroblasts
		<i>In vivo</i>	Adenovirus	Neuronal cells
Parkinson's disease	TH	<i>Ex vivo</i>	Retrovirus	Fibroblasts
			Adenovirus	Neuronal cells
AIDS	HSV-TK, HIV antigen, RevM10	<i>Ex vivo</i>	Retrovirus	T cells
	Cytokine			Hepatocytes
				Hematopoietic stem cells

Abbreviations: CFTR, Cystic fibrosis transmembrane regulator; SCID, severe combined immunodeficiency syndrome; DMD, Duchenne muscular dystrophy; ADA, adenosine deaminase; HSV-TK, herpes simplex virus thymidine kinase; NGF, nerve growth factor; TH, tyrosine hydroxylase; LDL, low density lipoprotein; tPA, tissue plasminogen activator.

REVIEW ARTICLES

of therapeutic interest such that the virus can only infect and deliver the therapeutic gene to the host but cannot replicate or cause disease. Of the various viruses that are being manipulated this way, research on retroviruses, adenoviruses and adeno-associated viruses has progressed very rapidly and deserves to be discussed in greater detail.

Viral vectors

Retroviruses as gene transfer vehicles have gained prominence because intense research on these viruses in the last two decades has generated a great deal of information on the biology and safe handling of these viruses. The work-horse for retroviral gene therapy has been the murine leukemia virus (MLV), although efforts are under way to develop HIV-based vectors so that even non-dividing cells can be infected. The first step in the development of a replication-defective recombinant retroviral vector involves the replacement of viral structural genes such as *gag*, *pol* and *env* by the therapeutic gene of interest. This vector is then transfected into a packaging cell line that provides the viral structural proteins *in trans*, so that the recombinant retroviral genome, by virtue of its packaging signal (ψ), is packaged and replication-defective retroviruses are generated. When such viruses infect the host cells, the recombinant retroviral RNA is reverse transcribed and integrated randomly into the host genome. In the absence of viral genes, the therapeutic gene is transcribed from the viral LTRs or in some cases from an internal promoter and the protein of interest is synthesized (Figure 1). Depending on the envelope protein produced in the packaging cell lines, one can generate either ecotropic viruses (which can infect rodent cells) or amphotropic viruses (capable of infecting other species including human)^{5,6}. Retroviruses can infect any cell type and in order to impart specificity, the wild type envelope proteins are being modified to include proteins that can dock with specific cell surface receptors, so that they can be targeted to specific cell types. For example, an ecotropic virus which cannot infect human cells can be engineered to infect human cells expressing erythropoietin receptor, by replacing 150 amino acids of the virus envelope protein with that of erythropoietin⁷. In a different approach, the viral envelope protein was converted into an asialoglycoprotein by coupling chemically to lactose and such a virus was able to infect specifically hepatocytes which contain the asialoglycoprotein receptors. Transgene expression can also be made tissue-specific by using internal promoters that function only in specific tissues. Another improvement involves the inclusion of internal ribosome entry sites to promote cap-independent translation initiation at internal initiation codons so that multiple proteins can be expressed from a single poly-

cistronic mRNA⁶. Several steps have been taken to prevent the generation of wild type virus such as expression of structural genes in the packaging cells under different eukaryotic promoters, mutation of the residual AUG codon in the recombinant vector, etc., so that even multiple recombination events are unlikely to generate wild type retroviral particles. The major concern of retroviral gene transfer is the insertional mutagenesis of growth regulatory genes during retroviral integration which could lead to cancer. Retroviral vectors are used mostly in *ex vivo* gene transfer experiments, although it has been shown that they can infect a regenerating liver when administered intravenously into a hepatectomized animal⁸.

Adenoviruses can infect a wide range of cell types and live adenoviruses have been used as vaccines in US military personnel without any major side effects. Two serotypes, Ad5 and Ad2 have been extensively studied, the genome has been (36 kb DNA) sequenced. Of the several genes encoded by the adenoviral genome, the proteins encoded by the E1 gene are crucial for virus replication and deletion of E1 gene renders the virus replication defective. Therapeutic genes up to 3.2 kb can replace the E1 gene and introduction of the recombinant viral DNA into cells expressing the E1 gene products results in the generation of replication-defective adenoviruses^{9,10}. Genes up to 7.5 kb can be accommodated by deletion of another non-essential gene,

Figure 1. Retroviral gene transfer. Construction of a retroviral vector, production of recombinant retroviruses, transfection of target cells and synthesis of recombinant protein are shown (see text for details).

E3. Adenoviruses are attractive candidates for gene therapy of lung disorders because of their natural tropism for infecting respiratory epithelium¹¹. Unlike retroviruses, they can infect post-mitotic cells as well and this has raised the possibility of their use for gene transfer into brain^{12,13}.

Adeno-associated virus (AAV), a non-pathogenic human parvovirus has aroused a lot of interest as a vector for gene therapy. AAV is a dependovirus and requires a helper virus coinfection for viral replication. In the absence of coinfection with a helper virus such as adenovirus, herpes virus or cytomegalovirus, the viral genome integrates into the human genome usually at a specific site, 19q13.3-qter. The therapeutic gene of interest is cloned between the two inverted terminal repeats or ITRs and the recombinant plasmid is transfected along with another plasmid expressing the viral structural proteins, Rep and Cap into cells infected with a helper virus. The recombinant AAV particles thus generated are purified and used for infection of target cells. The biology of AAV vectors is not as well understood as that of retroviruses or adenoviruses and this vector system is still in its infancy. The potential use of this virus as a gene transfer vector has intensified research on the life cycle of the virus and understanding the mechanism of latency, site-specific integration and development of good packaging cell lines will be the key to the success of AAV as a vector for gene therapy².

Non-viral approaches

Despite the fact the most of the research in gene therapy has focused on the development of viral vectors, the clinical efficacy as well as safety of these methods is still questionable. Further, the technical complexity and cost of performing viral-based gene therapy is another factor that has led to a resurgence of interest in the development of non-viral gene therapy. Unlike the viral vectors, which are used in both *in vivo* and *ex vivo* strategies, majority of the non-viral methods follow the *in vivo* approach, so that a successful non-viral technique can lead to the possibility of using genes directly as drugs. In general, non-viral methods for gene transfer can be categorized as physical and chemical methods. Of the various chemical methods, delivery of genes complexed with ligands for cell surface receptors and cationic lipids have been under intense study. The concept of delivering genes into specific tissues via receptor-mediated gene delivery was examined extensively with the liver asialoglycoprotein receptors. These receptors which are exclusively present on hepatocytes bind to certain glycoproteins lacking the terminal sialic acid. The strategy has been to couple orosomucoid (an asialoglycoprotein) to poly-L-lysine and the conjugate is condensed with plasmid DNA via electrostatic interactions.

The resulting soluble complex when injected intravenously, is internalized into hepatocytes via the asialoglycoprotein receptors and transgene expression was detected up to several weeks¹⁴ (Figure 2). This strategy was later extended to other cell surface receptors such as transferrin receptor, etc.¹⁵. While the receptor-mediated gene delivery is an attractive strategy as it takes advantage of the normal physiological pathway, the major problem has been the degradation of DNA by the lysosomal enzymes in the endosomes. Co-administration of lysosomotropic agents such as chloroquine has been shown to enhance gene expression. Since adenoviruses escape lysosomal degradation by acidification of endosomes, several strategies have been designed to develop adenovirus-linked molecular conjugate vectors. For example, monoclonal antibodies against a heterologous epitope on the hexon protein of the adenovirus envelope is covalently linked to polylysine which was then coupled to plasmid DNA. Such a conjugate can now interact with adenoviruses expressing the epitope on the envelope and delivery of such molecular conjugates has been shown to facilitate more efficient gene transfer than that by the conventional receptor-mediated gene delivery techniques¹⁶. In their present form, molecular conjugate vectors have several applications for *in vitro* use, but use in somatic gene therapy awaits more improvements in the vector design and delivery.

The observation that positively charged liposomes or cationic lipids can entrap negatively charged DNA has led to the possibility of their use as gene transfer vehicles *in vivo*. Several cationic lipid formulations are now being used for transfection of cells in culture and

Figure 2. Receptor-mediated gene delivery. The delivery of asialoglycoprotein-poly-L-lysine-DNA complex (ASGP-PL-DNA) into hepatocytes, its internalization into hepatocytes via the asialoglycoprotein receptor (ASGPR), delivery of DNA into the nucleus and synthesis of recombinant protein are depicted.

some of these have been shown to promote gene delivery into a variety of organs *in vivo* as well^{17,18}. Two potential applications of cationic lipids are the aerosol delivery of genes to lungs and in the development of cancer vaccines. The cationic lipid-mediated gene delivery to lung has advantages over adenovirus-mediated gene transfer in that, it can be administered as an aerosol and is non-immunogenic. Intratumoral injection of DNA-lipid complexes is being attempted to evoke specific immune response against a given tumour type by expression of heterologous antigens, cytokines and co-stimulatory molecules^{19,20}.

Amongst the physical methods of gene transfer, direct DNA injection into skeletal muscle has created a lot of excitement and has led to the possibility of using genes as vaccines. Several researchers had attempted direct gene transfer since the early 1960s, but these studies were not taken seriously due to inefficient gene transfer and low levels of expression. It was in the year 1990, Wolff *et al.*²¹ reported that direct injection of plasmid DNA into skeletal muscle results in sustained expression of foreign genes but the level of expression is too low to derive a therapeutic benefit for the treatment of genetic disorders. However, researchers at Vical and Merck pursued these studies further and demonstrated that the low levels of foreign proteins synthesized in the host cells were processed along the Class I MHC pathway, leading to presentation of peptides on cell surface resulting in a potent immune response against the foreign antigens and thus was born the concept of DNA vaccine or genetic immunization. These researchers demonstrated that immunization by direct injection of plasmid DNA encoding influenza nucleoprotein protects mice from a lethal challenge of influenza virus²². In the last few years, these results were confirmed with a variety of genes encoding several viral and parasite antigens and many of these studies have now been approved for clinical trials in the United States. Direct injection of plasmid DNA encoding foreign antigens into skin has also been shown to evoke a protective immune response. Another physical method of gene transfer that is becoming popular is the delivery of DNA using 'gene gun'. This method, developed originally for transformation of plants, involves delivery of genes by bombardment with gene-coated gold particles into tissues such as liver, skin, mammary gland and muscle. Direct gene delivery is now being used to map promoter elements that regulate gene expression *in vivo*, in transfection of herpes simplex thymidine kinase genes into melanomas to render them sensitive to gancyclovir and as a vaccination strategy²³⁻²⁶. Thus, direct gene transfer is one example of a technique that failed to make an impression in the treatment of genetic disorders but made an enormous impact in the field of vaccine development and is being heralded as the third vaccine

revolution. Other physical methods such as electroporation and microinjection have only limited scope in somatic cell gene therapy and their use is largely restricted to transfection of cells in culture and transgenic animal research.

The success of gene therapy depends not only on the gene delivery mechanism but also on the choice of target tissues. Cell types which can grow and divide *in vitro*, such as keratinocytes, myoblasts, hepatocytes, endothelial cells and hematopoietic stem cells, are amenable for both *ex vivo* and *in vivo* gene delivery strategies whereas *in vivo* methods are preferred for cell types such as neuronal cells which are not easily amenable for *ex vivo* manipulations. The choice of tissue also depends on the function of the gene product. In case of diseases such as hemophilia, the gene can be delivered and expressed in any tissue, provided that the protein is released into the blood stream. In case of diseases such as cystic fibrosis and Duchenne's muscular dystrophy, the gene should be delivered to the specific cell types where the gene function is deficient, in order to derive the therapeutic benefit. Further, the ease and efficiency with which the transfected cells can repopulate the affected tissue is another criterion that poses limitations on *ex vivo* gene therapy. One of the main targets for *ex vivo* gene therapy is the hematopoietic stem cells and retroviral gene transfer has been the most preferred method of gene transfer into these cells. In case of gene therapy for neurological disorders, gene transfer is being attempted using adenoviral and herpes viral vectors. While *ex vivo* gene transfer is usually performed with autologous cells, heterologous cells or even immortalized cells placed in immuno-isolation devices have been used, although the potential safety concerns make them less attractive for use in humans²⁷. Antisense gene transfer is another attractive strategy for the treatment of disorders such as β -thalassemia, in which accumulation of α -globin chains in red blood cells results in their premature destruction. For example, infection of K562 erythro-leukemia cells with AAV expressing human α -globin gene in antisense orientation results in significant inhibition of the endogenous α -globin gene²⁸.

The potential of a gene delivery system is first ascertained in cultured cells or in animal models, using reporter genes such as luciferase, growth hormone, β -galactosidase, etc. Based on these studies, pre-clinical trials are conducted in animal models to evaluate the levels and duration of expression of specific therapeutic genes. The clinical efficacy of the gene therapy procedure is then evaluated in human patients. Prior permission from specific regulatory agencies is necessary for performing gene therapy in humans. The Recombinant DNA Advisory Committee (RAC) and the Food and Drug Administration (FDA) in the United States and the Gene Therapy Advisory Committee (GTAC) in the United

Kingdom are empowered to authorize the conduct of such clinical trials in these countries. Several other countries such as The Netherlands, Italy, Germany, France, China, Japan, Switzerland, Sweden and Austria have also evolved guidelines for gene therapy research and initiated clinical trials for human gene transfer. These guidelines are being formulated in India as well.

Problems and prospects

The viral and non-viral gene delivery strategies have been fairly successful in cell culture systems and animal models but the therapeutic success of clinical trials in humans still remains questionable. Two types of clinical trials are being conducted in humans using these vectors: gene marking and therapeutic studies. In gene marking experiments, human cells which have a potential therapeutic use, such as hematopoietic stem cells, T cells, tumour-infiltrating lymphocytes, malignant cells, etc., are removed from the patient, cultured and transfected with retroviral vectors encoding marker genes and re-introduced into the patient from whom the cells are removed. At different periods after re-introduction, cells are recovered and the presence of marker gene or its products is examined. Such studies have demonstrated that gene transfer is feasible in humans and depending on the vector system used, marker gene expression could be detected for a period ranging from a few days up to three years²⁹⁻³¹. Cell-marking studies have also been used to detect residual cancer cells in the marrow infused into patients during autologous bone marrow transplantation, for treatment of diseases such as leukemia²⁹. Thus, cell-marking studies have been very useful in demonstrating the feasibility and safety of human gene transfer, especially using the retroviral vectors. On the contrary, the therapeutic trials are aimed at transfer of therapeutic genes into patients for treatment of specific genetic disorders and cancer. Several therapeutic clinical trials have been initiated in the last few years and the results of some of these are now available. Some examples of successful *ex vivo* human gene transfer studies are: transfer of adenosine deaminase (ADA) gene transfected T cells or cord blood cells to children suffering from adenosine deaminase deficiency leading to severe combined immunodeficiency (SCID)³²⁻³⁴, transfer of autologous cells encoding cytokine genes into cancer patients, transfer of autologous hepatocytes encoding low-density lipoprotein (LDL) receptor for individuals with familial hypercholesterolaemia³⁵, intracerebral transfer of fibroblasts expressing herpes simplex virus thymidine kinase gene for the ablation of brain tumours³¹, etc. Examples for successful *in vivo* gene transfer are: delivery and expression of the gene encoding cystic fibrosis transmembrane conductance regulator (CFTR) in the pulmonary epithelium of cystic fibrosis patients using

adenoviral vectors and cationic lipids^{36,37}; human leukocyte antigen (HLA-B7) and β 2-microglobulin gene transfer in tumours by cationic lipid-mediated gene transfer^{38,39}, etc. In many of these clinical trials, patients continued to receive conventional drug and/or protein replacement therapies along with gene therapy leading to difficulty in the interpretation of results. These problems are discussed below with specific examples:

In the year 1990, a clinical trial was initiated in two children suffering from ADA deficiency, using an *ex vivo* retroviral gene transfer protocol involving autologous T cells isolated from these patients³⁴. Prior to gene therapy, these children were undergoing enzyme replacement therapy wherein bovine ADA conjugated with polyethylene glycol (PEG-ADA) was being administered at regular intervals for 2-4 years. In the gene therapy approach, T cells were isolated from these children, induced to proliferate *in vitro* and then transfected with a retroviral vector encoding the normal ADA cDNA. Such genetically modified lymphocytes were expanded in the laboratory and periodically infused into the autologous patients for two years and the effect of the therapy was evaluated for a period of five years. However, enzyme replacement therapy was also continued during this period and several clinical parameters such as increase in T cell numbers, ADA levels in the circulating T cells, T cell cytokine release, cytotoxic T cell activity and skin test response to common antigens were evaluated over a period of five years. Comparison of these parameters with those observed prior to the commencement of gene therapy indicated a definitive improvement, although the continued enzyme infusions during this period makes it difficult to evaluate the benefit derived from gene therapy alone. The problem with this clinical trial has been the variation in the level of ADA⁺ circulating T cells seen in these two patients, which varied from 0.1 to 60%. Nevertheless, this study demonstrated that *ex vivo* retroviral gene transfer is a feasible and safe strategy for the treatment of ADA deficiency and several protocols, each using different strategies involving different retroviral vectors targeted to different cell types have been approved for clinical trials and results of these studies are still awaited³⁹.

Familial hypercholesterolaemia is another genetic disorder that was the target for *ex vivo* retroviral gene therapy for a long time. This genetic defect, resulting in deficiency of LDL receptors in the liver, results in high levels of serum cholesterol and LDL cholesterol, leading to premature atherosclerosis and myocardial infarction. The gene therapy protocol for the correction of this disorder involves isolation of hepatocytes from the patient by partial hepatectomy, *in vitro* transfection with retroviral vectors carrying a normal LDL receptor gene and reintroduction of these genetically modified hepatocytes into the portal circulation of the patient.

Studies were first carried out in rabbits, later in dogs and baboons and long term expression (up to 1.5 years in baboons) of the foreign gene was demonstrated in these animals. Based on these results, a clinical trial was initiated in a 28-year-old French Canadian woman on 5 June 1992, suffering from this genetic disorder³⁴. Evaluation of molecular and metabolic data over a period of 18 months after gene transfer suggested that the genetically modified hepatocytes had engrafted stably in this patient, recombinant gene expression could be detected throughout this period and there was a significant reduction in LDL cholesterol and LDL/HDL ratio. However, similar to the ADA-deficiency studies, this study was also compromised by the fact that other conventional therapies were being administered during this period. Despite this drawback, the study demonstrated that liver-directed *ex vivo* retroviral human gene therapy is a feasible and safe approach and can be applied for the treatment of other hepatic genetic disorders as well.

Of the *in vivo* approaches, introduction of adenoviral vectors encoding the normal CFTR to the nasal or bronchial epithelium of patients with cystic fibrosis has been shown to result in the expression of CFTR in the lung epithelium^{36,37}. CFTR cDNA containing plasmids have been directly administered to the nasal epithelium of these patients via cationic lipid-mediated gene transfer. In all these clinical trials, evidence for transfer of normal CFTR gene into the respiratory epithelium was clearly established, however, expression is observed in only about 5% of the target cells³¹. Further, the clinical efficacy, assessed by the correction of abnormal potential difference across the nasal epithelium, is observed in only some of the patients who have undergone gene transfer. Another problem associated with adenoviral gene transfer to the lung is the local and systemic inflammatory response evoked in some patients which was not observed in animal trials³⁹.

In addition to the treatment of genetic disorders, the gene transfer techniques have also been applied extensively in the treatment of cancer and other acquired disorders. The cancer gene therapy strategies are of two types: correction of abnormal genotype of the tumour cells or destruction of tumour cells. The corrective gene therapy is aimed at introducing wild type tumour suppressor genes or genes encoding dominant negative mutants of oncogenes that are mutated in the tumour cells⁴¹. The major limitation of this approach has been the difficulty in delivering the corrective gene into every tumour cell. Thus, efforts are largely centered on the alternative approach aimed at destruction of the abnormal tumour cells by expression of genes encoding cytokines or toxins. Autologous tumour cells are modified *ex vivo* by the transfer of genes encoding cytokines, allogenic MHC molecules or heterologous antigens to enhance their immunogenicity⁴². Another strategy has been to

introduce genes encoding cytokines or tumour necrosis factor into tumour-infiltrating lymphocytes (TILs) and their autologous transfer into cancer patients⁴³. In the cytotoxic gene therapy approach, genes encoding enzymes such as herpes simplex thymidine kinase, cytosine deaminase, etc., are cloned downstream of tumour-specific promoters and introduced into tumour cells. These enzymes convert pro-drugs into toxins that destroy the tumour cells. Surprisingly, even non-transfected neighbouring cells are destroyed and this bystander effect is probably due to the transfer of the toxins between cells via cell-junctions^{41,44}. Despite promising results obtained in animals, there is no convincing evidence that any of the gene therapy protocols actually led to regression of tumours in humans. Thus, the problem of inconclusive and inconsistent results obtained from clinical trials of gene therapy for genetic disorders is also true for that of cancer⁴⁵.

In the final analysis, it is clear that the move from mouse to man is not going to be easy. The conduct of clinical trials has been a great education and we now have a fair knowledge of the actual problems and pitfalls of the various gene delivery strategies. None of the clinical trials conducted so far could convincingly demonstrate the therapeutic benefit of gene therapy and has not been as effective as expected⁴⁶⁻⁴⁸. This is in sharp contrast to the results obtained in animal experiments which raised the expectation of gene therapy so much that the potential of gene transfer strategies became greatly exaggerated and mere conduct of a clinical trial led to a steep rise in the stock market prices of companies involved in gene therapy research. While nobody debates the importance and long term potential of human gene therapy, it is now clear that the current gene transfer techniques are largely inadequate to promote sustained, high level expression of foreign genes *in vivo*. Thus, in order for gene therapy to become a reality, it is essential that more efforts are directed towards understanding the pathophysiology of diseases as well as the mechanism of gene regulation *in vivo*. More basic research should be initiated into vector development and the role of chromatin, enhancers and locus-control regions in the regulation of gene expression *in vivo* has to be investigated in greater detail. Despite the various setbacks, gene therapy has witnessed a rapid growth in the last decade and fundamental advances made in molecular and cell biology will continue to contribute to the progress of gene therapy. For example, a recent study on hereditary tyrosinemia type I indicates that as few as 1000 transplanted hepatocytes can repopulate almost an entire liver, suggesting that retrovirally transfused hepatocytes can be induced to engraft into host liver and proliferate extensively, when appropriate selective pressures are applied⁴⁹. Such studies could solve the problem of low efficiency of gene transfer and bring

ex vivo hepatic gene therapy much closer to reality. Gene therapy is yet to become a dream come true, but the light is seen at the end of the tunnel!

Need for gene therapy studies in India

With the explosive increase in the availability of information on human genome, several genetic disorders would become candidates for gene therapy. As already indicated, besides genetic diseases, gene therapy has the potential for treatment of several other disorders such as cancer, cardiovascular and neurological disorders and infectious diseases. At the same time, the initial hype and euphoria are giving place to a realistic assessment of the basic information that is needed to make this exciting approach a success. This 'back to the basics' approach lends tremendous scope to initiate fundamental studies on (i) design of newer vectors for gene delivery, (ii) newer approaches to systemic delivery, (iii) targeting to specific tissues and cells, (iv) stability and duration of expression of the gene introduced, (v) The status of the introduced gene *in vivo* – integrated into the chromosome or episomal?, (vi) design of appropriate animal models, (vii) assessment of risk-benefit status, and (viii) an understanding of the molecular basis of cellular humoral immune response in case of DNA vaccines.

At the present stage, only 3 or 4 laboratories have initiated research in this area in the country. At Delhi University (South Campus), delivery of macromolecules such as toxins, drugs and nucleic acids into viable cultured cells through the use of reconstituted sendai virus envelopes (RSVE or virosomes) has been demonstrated^{50,51}. Since this involves fusion and delivery of genes into the cytoplasm, receptor-mediated delivery into lysosome and consequent degradation in the endosomes is circumvented. This approach needs to be extrapolated under *in vivo* conditions. At the Cancer Research Centre Bombay an approach to treat oral cancer through gene targeting to oral mucosal cells is under examination. In our laboratory, receptor-mediated targeting and expression of growth hormone gene in rat liver have been demonstrated with the use of a regulatable promoter (cytochrome P-450 promoter induced by phenobarbital)⁵². Further, newer approaches to delivering DNA to hepatocytes by perfusion of liver with DNA-lipofectin complex have been demonstrated⁵³. More recent studies have involved a comparative study of the efficiency of different carriers and routes of injection on the uptake and expression of reporter genes in experimental animals both from the perspective of gene therapy and DNA vaccination. Non-viral gene delivery strategies are being examined for their therapeutic and vaccination potential using expression vectors encoding growth hormone and antigens of rinderpest virus. There is scope to extend these genetic immunization studies to other models in-

volving Japanese encephalitis virus, malarial parasite, etc.

The need of the hour is to initiate more studies in different systems on the various aspects mentioned earlier. The field is still at its infancy and relevant. For the first time in the history of mankind, a rational approach to actually treating a genetic disorder has become at least an experimental feasibility. A welcome fallout has been the potential of this approach to treat cancers in particular. Recognizing the importance and relevance of this approach, the Department of Biotechnology has constituted a group of experts to activate this area of research and invite proposals. It is to be hoped that the scientific community in the country would come forward to work in this area of biomedical research that lends scope for collaboration between medical and basic research scientists.

Micelles: Self-organized surfactant assemblies

S. P. Moulik

Center for Surface Science, Department of Chemistry, Jadavpur University, Calcutta 700 032, India

Surfactants can self-organize under specific environmental conditions in solution to form 'micelles'. The micelles are of two types, 'normal micelles' (called micelles), which are formed by surfactant association in water or polar solvents, and 'reverse micelles', which are formed in nonpolar media. The surfactants and micellar solutions have versatile uses in the fields of chemistry, biochemistry, pharmacy, medicine and industry to augment and control solubilization, stabilization, dispersion, cleaning, rates of chemical reactions, enhanced oil recovery, etc. In this review, fundamentals of formation of micelles, their physico-chemical properties and probable uses are presented for an overall grasp of the topic of contemporary interest.

AMPHIPHILES are chemical compounds having dual affinity for water and oil. They have distinct nonpolar (lipophilic or hydrophobic) and polar (hydrophilic or liophobic) sections in their molecules. Soaps, detergents, long chain alcohols (amines, aldehydes, etc.) and lipids constitute the class of amphiphiles. They are surface active, can reduce surface tension of the medium or interfacial tension between two immiscible liquids (e.g. oil and water), can assist solubilization, cleaning, dispersion, emulsification, etc. The amphiphiles comprising soaps and detergents show a special property in solution manifesting characteristic self-organization or association

called 'micelle' formation^{1,2}. Under appropriate conditions, amphiphiles (mostly of lipid types) may also form 'liquid crystals' in solution. The amphiphiles that form micelles and can be potentially used for surface chemical works are termed SURFACE ACTIVE AGENTS or SURFACTANTS. Soaps and detergents come under this heading. Soaps are prepared by the hydrolysis (saponification) of naturally occurring fats and oils, and detergents are synthetically prepared. Big industries are busy with the production of soaps and detergents all over the world. The innumerable possibilities of such products through chemical modification and synthesis and great many uses of amphiphiles in pharmaceutical, chemical, biochemical (including biomedical) and industrial fields have added tremendous scope of research and study in this area of surface and colloid science and technology. The investigations on micelles comprise a significant share in this area, a comprehensive accounting of which is of contemporary interest. In the following sections, the overall state of the art of basic aspects of surfactants and micelles including their potential uses are presented.

Types of micelle-forming amphiphiles or surfactants

The micelle-forming amphiphiles or surfactants essentially fall in two categories, 'ionic' and 'nonionic'. They

basically contain nonpolar polymethylene chain (called the tail) and an ionic or polar group (called the head). The nonpolar tail may have substitution and they may contain phenyl rings; the polar or the ionic head group may have distinctive variations. Table 1 gives examples of several typical micelle-forming amphiphiles whose solution properties have been extensively studied and have potential for future investigative inclusions.

The examples given in Table 1 are only a few of the vast number of surfactants possible directly from natural sources and through synthesis³. It is imperative that numerous possibilities of formation, by way of synthesis, exist.

Requirements for micelle formation

Molecular factor

As stated above, all amphiphile molecules have a distinct hydrophobic (HP) tail and a hydrophylic (HF) head (Figure 1).

Table 1. Examples of typical ionic and nonionic micelle forming amphiphiles^a

Ionics	Nonionics
Sodium palmitate	Polyethylene glycol tertoctyl phenyl ether (Triton $\times 100$)
Sodium oleate	Sorbitan monolaurate (Span 20)
Sodium decyl sulphate (NaDes)	Sorbitan monopalmitate (Span 40)
Sodium dodecyl sulphate (SDS)	Sorbitan monostearate (Span 60)
Sodium dodecyl sulphonate	Sorbitan monooleate (Span 80)
Sodium dodecyl benzene sulphonate (SDBS)	Polyoxyethylene (4) laurylether (Brij 30)
Sodium cholate (NaC)	Polyoxyethylene (23) laurylether (Brij 35)
Sodium deoxycholate (NaDC)	Polyoxyethylene (9) palmitylether (Brij 56)
Sodium chenodeoxycholate (NaDC)	Polyoxyethylene (9) stearylether (Brij 76)
Sodium taurochenodeoxy cholate (NaTCDC)	Polyoxyethylene (20) sorbitan monolaurate (Tween 20)
Sodium bis ethyl hexyl sulfo-succinate (AOT)	Polyoxyethylene (20) sorbitan monopalmitate (Tween 40)
Dodecyltrimethyl ammonium bromide (DTAB)	Polyoxyethylene (20) sorbitan monostearate (Tween 60)
Tetradecyltrimethyl ammonium bromide (TTAB)	Polyoxyethylene (20) sorbitan monooleate (Tween 80)
Hexadecyl (or cetyl) trimethyl ammonium bromide (CTAB)	Octylmethyl sulphoxide
Hexadecyl (or cetyl) pyridinium chloride (CPC)	Tetradecyl <i>N</i> betaine

^aFor ionics, abbreviations are given in parenthesis. They are commercial identities for nonionics. The numbers in parentheses correspond to the number of polyoxyethylene groups.

Depending on the molecular structure and type, a balance between the hydrophilicity and hydrophobicity exists in the molecule. This is called hydrophilic-liphophilic-balance or HLB, which is important in categorizing surfactants as emulsifiers, detergents, wetting agents solubilizing agents, micelle-forming types, etc⁴. It is imperative that surfactants having greater hydrophobicity are more surface active and vice-versa. In solution, mutual likings (interaction) between surfactant molecules, solvent (water) molecules, and surfactant and solvent molecules decide the ultimate state. When self-interactions of both surfactants and solvent molecules cannot be compensated by their mutual interactions, the surfactant molecules tend to associate in a regular pattern forming 'association colloids' or 'micelles'⁵. Instead of crowding at the interface, the amphiphiles hide their tails in the micellar interior creating similar (oily) environment, with their hydrophylic heads remaining out in the aqueous medium. It has been observed that micelle-forming amphiphiles in a homologous series need to have eight or more methylene (CH_2) groups in the chain, lower number cannot conveniently augment nonpolar association of the tails to overweigh the head group repulsion and hydrophilicity culminating to micelle formation (Figure 2).

Physical factors

It is imperative that micelle formation becomes easier for surfactants having greater hydrophobicity (or increased chain length) in a homologous series. The other factors that can influence or control the phenomenon are solvent polarity and type, temperature, presence of additives (salts, etc.) and pressure⁵.

The polarity of the medium favours surfactant association. Nonpolar medium offers environment similar to the surfactant tail so that their tendency of self-association is reduced. In a good nonpolar medium, viz. cyclohexane, carbon tetrachloride, hydrocarbons (heptane, octane, decane, etc.), formation of normal micelle as figured above may be totally absent; instead a reverse orientation of the surfactants with tails out and head groups in the

Figure 1 a-c. Perspective representations of surfactants. *a*, ionic; *b*, nonionic; *c*, zwitterionic.

micellar interior may occur; such entities are called 'reverse micelles'. A trace amount of water helps easier and stable formation of reverse micelles. This will be briefly discussed in a subsequent section.

The effect of temperature on micelle formation is essentially guided by the way temperature affects the solubility and other behaviours of surfactants in solution. Normally, surfactant solubility in water does not radically increase with temperature. Desolvation and changed solvent structure play a significant role in this respect. In general, micelle formation is favoured with increase of temperature in the lower range of temperature, at higher temperature range, the formation is disfavoured. The desolvated head groups may end up with greater electrostatic repulsion to resist micelle formation. The situation becomes complex by the changed polarity of the medium at higher temperature. Thus an overall comprehension⁵⁻⁷ of the effect of temperature on the phenomenon of micellization may not be straightforward. At higher temperature, desolvation of the polar head groups of nonionic surfactants leads to phase separation, the solution becomes cloudy. The temperature at which the phenomenon starts is called the 'cloud point'⁵⁻⁸. The temperature stability of nonionic surfactants is often judged by their cloud points.

The surfactants have characteristic temperature-dependent phase behaviours, a knowledge of which in solutions may be profitable for physical-chemical understanding of their solution behaviours. This is shown in Figure 3. In this diagram, there are three distinct zones A, B and C depending on concentration and temperature. In zone A, only surfactant monomers occur in solution. In zone B, monomers remain in equilibrium with micelles, whereas in zone C, monomer and precipitate (or crystals), i.e. a separate phase, exists in solution. This phase map is helpful in the preparation of a solution of a surfactant according to the need of its solution composition. At the point P all the three phases co-exist and by the phase rule, it is an invariant point. The corresponding

temperature is called Krafft temperature (T_K). To avoid or minimize the existence of precipitate, i.e. for the preparation of micellar solution at higher concentration (and only monomer solution at lower concentration), the working temperature should be above Krafft temperature (T_K) (refs 5, 9). The determination of T_K for surfactants is thus important.

The effect of pressure⁷ on self-organization of surfactants has been studied. Pressure initially retards the association and after a threshold value (100–200 MPa), the process is favoured. This is supposed to be a consequence of water structure destruction, by the applied thrust to assist wider distribution of the surfactant molecules in solution to oppose their tendency of association. The release of surfactant monomers from the micelles in the lower range of pressure and their association at higher pressure together with the changed dielectric constant of the solution by the application of pressure also play their specific roles in surfactant organization. This has been supported by the measurement of aggregation number which shows a minimum for ionic surfactants and a rapid initial decrease for nonionic surfactants with respect to pressure.

Additives may have significant effects on surfactant self-organization¹⁰. A salting-out effect of salts influencing the surfactant activity to assist easier aggregation may arise. The study of the influence of salt is important for in most occasions in chemical studies amphiphiles are handled in electrolyte environments. Non electrolytes may both increase and decrease micellization tendency of surfactants^{11,12}. The matter is complex because additives can influence solvent structure (fluidity) and polarity and can undergo direct interaction with the surfactants. In this regard urea and guanidine hydrochloride are conspicuous, they greatly hinder micellization and can break down water structure. The hydrophobic association and water structure destruction have a mutual correlation, a quantitative understanding of the phenomenon is still a matter of further research.

Figure 3. Temperature–[surfactant] profile showing different states in solution and the Krafft temperature, T_K .

Determination of micellar point

The phase map in Figure 3 indicates that under fixed environmental conditions, a threshold concentration is required for the formation of micelle. This threshold or critical concentration is called 'critical micelle concentration' or CMC. Its evaluation (determination) is an important physicochemical exercise for self-assembling surfactant solution.

A good number of methods can be used for the determination of CMC, viz. tensiometry, conductometry, viscometry, light scattering, fluorimetry, calorimetry, spectrophotometry, magnetic resonance, etc. The most frequently used methods are tensiometry, conductometry and fluorimetry, the conductance method is applicable only to ionic surfactants. The physical properties of surfactant solutions measured by different methods at different concentrations demonstrate a distinct feature as shown in Figure 4. The properties show breaks in the plots which are considered as the CMC points for the surfactants under investigation. It is to be noted that the CMC values determined by different methods fall in a narrow range, the CMC is moderately method-dependent. The significant increase in the scattered radiation above CMC in the light scattering method¹³ gives a direct proof of the formation of bigger species by self-association for the scattering phenomenon depends on the size of the scattering units. This and supports by other methods (e.g. self-diffusion by NMR)¹⁴ have established the correctness of the concept of micelles first proposed by McBain¹⁵ of USA (the first Director of the National Chemical Laboratory in independent India) which was severely but wrongly criticized by scientists in a Royal Society meeting in London.

Micellar properties and features

Micelles are surfactant aggregates having regular structures and shapes. From dimension and other considerations they are colloids; their sizes normally cover the range of 1–10 nm. The ionic micelle forms an electrical double layer¹⁶ surrounding it in the interfacial region (Figure 5). By virtue of surface charge and zetal potential, it exhibits electrophoresis under an applied electric field.

The micelles may assume different shapes, the spherical shape is most prevalent; ellipsoidal and cylindrical shapes are also not uncommon^{3,5,16} (Figure 2). The shapes may undergo transition, thus spherical micelles of sodium-dodecylsulphate change to cylindrical configuration in salt environment¹⁷. In presence of salicylates, cetyltrimethyl ammonium bromide, cetylpyridinium chloride, etc. can form long 'worm-like' micelles¹⁸. Such transition greatly influences (increases) the viscosity of the micellar solution, micellar mass increases significantly.

It is tempting to know the number of surfactant monomers that self-organize to form a micelle. The methods of light scattering and fluorescence quenching are conveniently used to estimate the aggregation number^{19,20}. Normally, the aggregation number falls in the range of 20–200; the bile salt micelles can have lower aggregation number²¹ of 4–10. The aggregation number varies with environmental variations. The transition from sphere to rod is associated with significant increase in the aggregation number²².

The presence of ionic groups at the micellar interface causes ion-dipole interaction and water molecules associate to solvate the micelles. The nonionic micelles arrest water molecules at the pallisade layer by hydrogen bonding of water with the polyethylene oxide groups²³. Water may remain trapped in this region. The interfacial properties of micelles are thus influenced by solvation. The solvation can be estimated by various methods, viz.

Figure 5a,b. Schematic representation of reverse micelles. a, in absence of water; b, in presence of water.

light scattering, IR-spectra, viscosity, electrophoresis, ultrasonic, etc. According to Hartley²⁴, the interior of the micelle is oil-like, the aqueous medium remains outside the interfacial boundary. Menger²⁵ has proposed that water can penetrate inside the micelle up to a certain level, the idea gets support from fluorescence and NMR measurements.

An ionic micelle forms an electrical double layer surrounding its boundary where by virtue of increased charge density, counter-ions are attracted and occupy positions in the 'stern layer'. A fraction of the counter-ions is thus bound²⁶ in the region which may considerably reduce the surface charge density. Information about the counter-ion binding is necessary for the understanding of the electrical double layer as well as accurate calculation of thermodynamics of micellization to be discussed subsequently. The electrochemical methods, viz. conductance and potentiometric are employed for the estimation of counter-ion binding²⁷. The extent of binding may be as high as 90%, quite a sizeable percentage of counter-ions may bind with the micelle greatly reducing the surface charge density and hence the double layer potential. The aggregation number and other properties, environmental variations can affect the counter-ion condensation of ionic micelles.

The polarity of the interior of micelles ought to be low like hydrocarbon oils. Fluorescence measurements²⁸ with suitable probes can estimate the magnitude of the polarity. A probe sitting at the interface should send the indication about the polarity of the interface. For information about the core, the probe should be well within the interior; an oil soluble probe would serve the purpose. The physicochemical properties of micelles are presented in Table 2.

Energetics of micellization

All physicochemical processes are energetically controlled. The spontaneous formation of micelle is obviously guided by thermodynamic principle. The matter is treated under two formalisms²⁹⁻³¹: (i) mass action principle, and (ii) 'pseudophase principle'. According to the first principle, above CMC, the concentrations of monomer and micelle are interdependent. Increase of monomer concentration increases micellar concentration and vice-versa in accordance with the following equilibrium

where S^- or S^+ or S = surfactant monomer; S_n^- or S_n^+ or S_n = micelle; n = aggregation number, and K_M = micellization constant with free energy of micellization (ΔG_M^0) = $RT \ln K_M$. At CMC, by conceptual approximation, the free energy of micellization expressed per mole of monomer unit ($\Delta G_m^0 = \Delta G_M^0/n$) is given by the relation,

Table 2. Physicochemical properties of some typical surfactants

Surfactant ^a	CMC/m mol dm ⁻³	Aggregation number	% Counterion bound
SDeS ⁴⁰	41.0	30	40
SDS ²⁵	8.0	50	60
AOT ²⁵	3.0	15	10
NaC ²⁰	12.0	2	—
NaDC ²⁰	5.0	4	—
NaTC ²⁰	10.0	4	—
DTAB ³⁰	16.0	48	77
TTAB ³⁰	3.1	55	73
CTAB ³⁰	0.8	55	85
CPC ³⁰	0.83	—	58
Triton X-100 ²⁵	0.03	134	—
Tween 20 ²⁵	0.05	86	—
Tween 40 ²⁵	0.023	92	—
Tween 60 ²⁵	0.021	112	—
Tween 80 ²⁵	0.01	124	—

^aSuperscripts refer to the temperature in °C. Abbreviations as in Table 1.

$$\Delta G_m^0 = RT \ln \text{CMC}. \quad (2)$$

Considering counter-ion binding to ionic micelles, eqn (2) is modified to

$$\Delta G_m^0 = (1 + f) RT \ln \text{CMC}, \quad (3)$$

where f = fraction of counter-ion bound to a micelle.

For nonionic surfactants, $f = 0$ and eqn (3) is reduced to eqn (2). It is seen that in case of ionic micelles, for accurate calculation of ΔG_m^0 , determination of f is a must.

In the pseudophase model, the monomer concentration at and above CMC remains nonvariant; with increasing surfactant concentration above CMC micelles are only formed. This is like solubility of a sparingly soluble salt where above the solubility limit excess amount separates out as the insoluble phase. The micellar pseudophase on the other hand remains in solution. Based on the phase equilibrium,

at a constant temperature, chemical potential of surfactant monomer in solution (μ_m) is equal to the chemical potential of the monomer in the pseudomicellar phase (μ_M) thus,

$$\mu_m = \mu_M. \quad (5)$$

Explicitly,

$$\mu_m^0 + RT \ln a_m = \mu_M^0 + RT \ln a_M. \quad (6)$$

Wherefrom we again get

$$\Delta G_m^o = RT \ln \text{CMC} \quad (7)$$

for nonionic micelle, and

$$\Delta G_m^o = (1+f) RT \ln \text{CMC} \quad (8)$$

for ionic micelle. The μ_m^o and μ_M^o are the standard chemical potentials of monomer and micelle respectively and a_m and a_M are their corresponding activities ($a_M=1$, for pseudophase is taken to be pure phase). The two models thus lead to the same interpretation of results. It is to be noted that in the above thermodynamic treatments, at the critical micelle concentration, the equilibrium concentration of free monomer is considered equivalent to CMC.

Applying Gibbs-Helmholtz equation, the standard enthalpy of micellization (ΔH_m^o) at constant pressure, P for nonionic micelles is given by the relation

$$\Delta H_m^o = -RT^2 \left(\frac{\partial \ln \text{CMC}}{\partial T} \right)_P = R \left(\frac{\partial \ln \text{CMC}}{\partial (1/T)} \right)_P \quad (9)$$

The entropy of micellization (ΔS_m^o) follows from the Gibbs equation,

$$\Delta S_m^o = \left(\frac{\Delta H_m^o - \Delta G_m^o}{T} \right) \quad (10)$$

The factor $(1+f)$ has to be included in the above relations for ionic micelles. The measurement of CMC at different temperatures is required for the evaluation of ΔH_m^o and ΔS_m^o . It is assumed that the aggregation number and counter-ion binding of the micelle are not affected by temperature variation at least in the range of measurements, which is not large in practice. Calorimetric measurements may offer direct determination^{32,33} of both CMC (i.e. ΔG_m^o) and ΔH_m^o at a constant temperature from which ΔS_m^o readily follows.

The ΔS_m^o values are essentially positive, negative values are seldom obtained^{16,34}. The micellization process therefore ends up with increase of entropy, an overall disorder state is envisaged. This is due to the release of solvent molecules attached with the nonpolar tails of surfactant monomers by hydrophobic hydration during self organization, the entropy gain by the process exceeds the loss by amphiphile association, solvation, etc., making the overall entropy change positive.

Mixed micelles

Mixed surfactants after a critical concentration should also micellize^{5,35,36} yielding CMC. The tendency is guided

by their attractive (synergistic) and repulsive (antagonistic) interactions. This is reflected in their CMC values compared to the CMC of their components. The occurrence of mixed surfactants and hence mixed micelles are common in industrial, pharmaceutical and biological fields; physicochemically, they work better than pure surfactants in solution. A schematic representation of mixed micelles is presented in Figure 6.

It is interesting to observe that although cationic and anionic surfactants may form insoluble ion-pairs at nearly equal molar proportions, they get solubilized if the proportion of one of them is appreciably larger than the other³⁷. Thus mixed micelles of ionic-ionic, ionic-nonionic and nonionic-nonionic combinations are possible whose physicochemical studies are required for formulations, uses and basic understanding.

The CMC of ideal mixtures of surfactants is given by Client's^{5,35} equation,

$$\frac{1}{(\text{CMC})_{\text{mix}}} = \sum_i \frac{\alpha_i}{(\text{CMC})_i} \quad (11)$$

where α_i and $(\text{CMC})_i$ are the mole fraction and CMC of the i th component respectively.

In most occasions the equation is not found to be obeyed, it may take the form

$$\frac{1}{(\text{CMC})_{\text{mix}}} = \frac{\alpha_i}{f_i (\text{CMC})_i} \quad (12)$$

where the new term f_i is the activity coefficient of the i th species.

There are recent theories³⁸⁻⁴⁰ to account for the mole fraction, activity coefficient, extent of interaction among the surfactants in the mixed micelles formed. The theories need improvement to account for all kinds of combinations, but the approaches are of considerable merit⁴¹. The propositions and equations are essentially on binary combinations, for higher combinations modifications are necessary. In mixed state, fundamental studies on binary systems are considerable, ternary combinations have been rarely investigated.

Figure 6. Schematic representation of ionic micelle showing counter-ion binding and the electrical double layer.

Reverse micelles

The micelles so far discussed are formed in aqueous medium. The surfactants may also self-assemble in non-polar solvents, viz. hydrocarbons, carbon tetrachloride, benzene, cyclohexane, chloroform, etc. They organize in a reverse manner, with their heads oriented towards the interior or core and the nonpolar tails towards the solvent. They are called 'reverse micelle'. In most occasions, the presence of water helps reverse micelles formation. Thus, there exists a tiny water core surrounded by the surfactant tails embedded in oil medium (Figure 7). Spectrophotometric, fluorimetric and calorimetric methods are used for the understanding of the beginning of their formation (i.e. CMC) and characterization⁴²⁻⁴⁴.

Dimensionally reverse micelles are comparable with normal micelles; both are thermodynamically stable. Their aggregation number and thermodynamics of formation can be assessed following the same arguments as for normal micelles. The counter-ion binding to the ionic surfactant head in the water pool of reverse micelles is difficult to estimate.

The reverse micelles can consume water or polar solvent in the interior, the core increases in size and may exceed micellar dimension. Such stable dispersions are called water-in-oil (W/O) microemulsions⁴⁵. In an analogous manner, normal micelles can accommodate oil to bulge in size forming oil-in-water (O/W) microemulsions. More addition of water and oil in the two categories of microdispersions ends up in the formation of bigger particle size yielding emulsions. Further discussion on this topic is beyond the scope of this article.

Uses of micelles

Micellar solutions are called 'compartmentalized liquids', the micelles serving as compartments which can help dissolution of polar and nonpolar compounds in normal and reverse micellar solutions respectively. This is an advantage which is not achieved otherwise. Solubilization and dispersion⁴⁶ are two important uses of micellar solution. During detergency, the micelles supply amphiphiles to act at the dirt-fabric interface for dislodging the dirt^{5,16,34} which finally is dispersed in the aqueous medium by their incorporation in the micelle for easy removal by washing.

About 50% of underground oil is recovered by pumping, and water as well as steam flooding, the rest 50% remains trapped in the pores and cracks of underground rocks which is difficult to recover. It has been established through research that by flooding micellar and microemulsion solution in the underground rocks, the interfacial tension between oil and aqueous solution can be greatly reduced to decrease the Laplace pressure under the curved oil meniscus in the pores to help mobilize

the oil for easy recovery^{16,47}. By this tertiary recovery or 'enhanced recovery' process another 30% of the underground oil can be recovered. But because of high price of surfactants etc. the method may not be on the whole cost effective. Further research in this direction has potential prospect.

The micellar solutions can influence reaction kinetics, both enhancement and retardation of the reaction rate may occur^{4,8,49}. Substrate binding and solubilization in the micelle are the main reasons for influencing the reaction kinetics. The activation barrier may be potentially affected. The reverse micelles may show significant influence on the reaction rates⁵⁰. Thus quick formation of products and often formation of new products can be achieved. Micellar kinetics are thus also compared with enzyme kinetics. It has been found that enzyme activities may also be enhanced and reduced by trapping them inside the aqueous pool of reverse micelles; the enzyme may show increased stability in compartmentalized liquids⁵¹⁻⁵³. The kinetics of substrate splitting etc. have been found to occur with altered efficiency; supra activities have also been reported. This has generated great impact of application of micellar medium-induced chemical and biochemical reaction processes.

The preparation of ultrafine monodisperse particles of colloidal dimensions is of great need in heterogeneous catalysis, magnetic tape production, biomedical application, etc. These can be conveniently prepared in compartmentalized (reverse micellar) media; thus microfine particles (often called nanoparticles) of desired sizes can be obtained through necessary chemical reactions^{54,55}. The oxides of iron, aluminium, chromium, nickel, etc.; sulphates of calcium, barium etc.; oxalates and phosphates of calcium, etc.; are examples of such materials which have prospects of preparation at the microfine monodisperse level by the above surface chemical method. The process of emulsion polymerization can be performed in reverse micelles for the preparation of polymers of controlled molecular weight and size. This is a significant advancement in the application of the micellar medium in technology.

Figure 7 *a, b*. Schematic representation of mixed micelles. *a*, normal micelle; *b*, reverse micelle.

Photochemical reactions are influenced by micellar medium^{15,56}; the interfacial region can affect the photochemical pathways changing the quantum yield. For example, in photo-decarbonylation of asymmetrical diaryl ketones of general formula ACOB in micellar medium, the yield of AB is very high compared to AA and BB which is much low without micelles⁵⁷. The molecule ACOB in a micelle essentially forms AB; the probability of reaction between two such molecules in two different micelles to form AA and BB is obviously very low.

Micellar solutions have prospects in carrier-mediated transport. A material otherwise insoluble can be captured by the micelle in one solution and is transferred into another. This principle is often used in phase transfer catalysis using micelles as carriers. Separation of proteins and other polar compounds by the use of reverse micelles has been demonstrated^{58,59}.

In presence of salt, anionic micelles undergo sphere to rod transition, making the solution viscous or thick. They undergo shear thinning assisting easier application. This principle is used in the preparation of shampoo which would be otherwise too watery to apply on hair¹⁵. Control of viscosity of preparations with nonionic surfactants is done by varying the length of the hydrophilic polyoxyethylene head group for effective surface wetting and detergency.

Pollutants can be solubilized by the micelles; both organic and inorganic pollutants are amenable to such conditions. Using micelles of desired size, they can be retained by the membrane while the solution is ultrafiltered for their removal^{60,61}. The surfactants can form chelate with metal ions aided by hydrophobic association, counter-ion binding can hold organic ions on them. They can be removed as well by ultrafiltration.

Micellar medium may be utilized for stereospecific reactions; one enantiomer may be favoured over another by virtue of strong orientational effects of polar amphiphilic reactants⁶².

Despite citing above a good number of avenues for profitable utilization of micellar medium, their large scale uses have become only limited. This is because of low substrate solubility, temperature and salt instability and difficulties in the separation of products from the surfactants. It is hoped that these hurdles will be overcome through exhaustive basic research and planned trials employing newly developed surfactants; until then the field remains challengingly open to scientists and technologists. The versatility of micellar solution is the key factor for its continued study and appropriate documentation.

Immunodiagnostic approaches to detect bovine tuberculosis

S. N. Joardar and A. Sikdar

Indian Veterinary Research Institute, Eastern Regional Station, 37, Belgachia Road, Calcutta 700 037, India

Even though tuberculosis is an ancient disease, its early diagnosis is still a global problem. Conventional diagnostic tests along with some improved techniques and molecular biological approaches have been reviewed. The current status and the pitfalls of the diagnostic procedures are reported. An attempt has also been made to give some insight of the future prospect of the field of research.

A recent report of the World Health Organization shows that multidrug resistant tuberculosis, which often leads to death, has emerged as a new global challenge. The

WHO, which has declared TB as a global emergency, has warned that the TB crisis will continue to grow unless immediate action is taken to stop its growth. The public health risk is more in agrarian countries like India, as bovine tuberculosis is a serious problem even now. The relationship between bovine tuberculosis and human tuberculosis has been reviewed earlier and it has been established that tuberculosis in cattle may be transmitted to man via milk, milk products, meat and directly in the cowbyre¹. The resurgence of the devastating disease has led to renewed interest in the development of improved diagnostic tests for tuberculosis in animals and a review of control measures.

The basis of the TB eradication programme in other countries has been systemic application of the standard tuberculin test and the slaughter of reactors. But in India test and slaughter method cannot be used due to high incidence of reactors and moreover, this procedure would result in the loss of highly productive cows and working animals. Hence, the accurate diagnosis of the infected animals remains a major concern for eradication of the bovine tuberculosis.

Early approaches

Efforts have been made to develop *in vitro* tests for tuberculosis. The conventional methods for detection and diagnosing bovine tuberculosis have been tried. A variety of serological tests, viz. complement fixation test^{2,3}, bentonite flocculation test^{4,5}, kaolin agglutination test⁶ and indirect fluorescent antibody test⁷ have been evaluated for the diagnosis of bovine tuberculosis. But these assays are less sensitive and less specific due to antigenic cross reactivity between mycobacteria often encountered by all mammalian species.

Cellular vs humoral immune response

It is well established that tuberculosis in both human and cattle induces a strong cellular response⁸⁻¹⁰ and hence a standard test for detection of cell-mediated immune response against tuberculosis in cattle should be targeted. The reaction mediated in a tuberculous cattle as a result of an intradermal injection of tuberculin, an antigenic extract derived from the tubercle bacillus, is of delayed hypersensitivity type. The reaction to tuberculin in a sensitized animal is an immunologically specific inflammatory reaction mediated by T cells. Because positive tuberculin reaction occurs only animals that have or have had tuberculosis, skin testing may be used to identify animals infected by this disease. But the tuberculin tests fails to detect some infected humans and cattle in advanced stages of the disease and it has been reported that the antibody responses in such cases of advanced disease were elevated^{10,11}. Therefore, a serological test coupled with a cellular test should give the greatest degree of accurate diagnosis¹². Moreover, the intradermal tuberculin test is known to lack both specificity and sensitivity due, in part, to the complex nature of the antigen purified protein derivative (PPD) used, which includes several cross-reactive proteins common to a range of other mycobacteria.

Improved diagnostic tests

Several workers recommended the use of enzyme linked immunosorbent assay (ELISA) as a complementary test

with tuberculin testing. The use of ELISA for bovine tuberculosis using tuberculin PPD as the source of antigen was first reported¹³ in 1983. Subsequently, it has been reported that ELISA can be used for the detection of *Mycobacterium bovis* infected animals, anergic to the tuberculin test. The specificity of ELISAs using sonicate preparations of *M. bovis* was reported to be low¹⁴. This may be due to the presence of higher concentration of the widely cross-reactive heat-shock proteins in these preparations compared with culture filtrate preparation¹⁵.

DNA synthesis is the most commonly measured parameter used for quantitative lymphocyte blastogenesis. This is usually accomplished by measuring the uptake and incorporation of radioactivity labelled base analogue or other molecules associated with cellular DNA synthesis. ³H-thymidine uptake measures the rate of DNA synthesis. ³H-thymidine uptake by tuberculin-stimulated lymphocytes is highly correlated with the degree of delayed skin reactivity. *In vitro* lymphocyte stimulation test tend itself as a practical and reliable test to aid in the diagnosis of *M. bovis* infection in cattle¹⁶. Lymphocyte transformation test is more sensitive and often positive when the skin test is negative, doubtful or feeble¹⁷. However, the incubation time and number of laboratory manipulations make it unsuitable for field work.

Therefore, a rapid, whole blood incubation system was developed and the release of a cytokine, interferon gamma (IFN- γ), as the indicator of a positive response to *M. bovis* antigen (bovine PPD) was proposed. A bioassay to detect the presence of IFN- γ , which showed good correlation with results obtained with the lymphocyte proliferation assay was developed initially¹⁸. Subsequently, monoclonal antibodies to recombinant bovine IFN- γ were produced¹⁹. These monoclonal antibodies were used to develop a sensitive enzyme immunoassay (EIA) for bovine IFN- γ (ref. 20). The bovine IFN- γ EIA when used in conjunction with the whole blood culture system resulted in a simple, rapid (24 h) and sensitive *in vitro* assay for detecting specific cell-mediated immune responsiveness in *M. bovis*-infected cattle. The IFN- γ assay has been accredited by the Standing Committee on Agriculture as a diagnostic test for bovine tuberculosis in Australia. The IFN- γ EIA is produced commercially and field trials of this assay, for the diagnosis of bovine tuberculosis, are currently in progress in the USA, New Zealand and Ireland²¹.

Molecular biological approaches

In the last couple of years, molecular biology has provided new approaches which have enabled detailed studies to be made of the molecular characteristics of *M. bovis*. These characteristics have been investigated for their potential use in diagnosis and epidemiological

REVIEW ARTICLES

studies. Restriction fragment analysis of genomic DNA from isolates of *M. bovis* has provided a highly discriminating typing system which has been extensively used for epidemiological studies. DNA elements in *M. bovis* have been investigated for their potential use in diagnostic assay based on the polymerase chain reaction (PCR). PCR-based diagnostic tests have the potential to detect DNA from a single organism of a predetermined species in a few days or less. This ability to provide a test that is specific and sensitive has encouraged development of many such tests for *M. tuberculosis* and these tests would also be expected to detect *M. bovis*. But unfortunately, techniques from sputum are not adequate for extracting very small number of *M. bovis* organisms from tissue lesions. Until this problem is overcome, diagnostic tests for *M. bovis* based on PCR will not have the sensitivity of current culture methods²².

Conclusion

Limited specificity and sensitivity is still a major problem in the development of a suitable diagnostic test for tuberculosis. Mycobacterial antigens consisting of a few or no crossreacting components, are needed to differentiate between tuberculous and non-tuberculous infections. In the past, efforts have been made to isolate specific antigen present in *M. bovis* BCG and *M. bovis* AN5 culture filtrates^{15,23-25}. Unfortunately, the cross reactivity of all the antigen purified so far was unacceptably high¹².

Recombinant mycobacterial antigen produced in *Escherichia coli* appears to be of limited use as diagnostic agents, because they are not consistently recognized by infected animals. The potential benefits of PCR assay approaches will remain the subject of intensive investigation. Hence, to identify the critical antigen(s) for the diagnosis of bovine tuberculosis, a lot more work is needed to improve the specificity without undue loss of sensitivity.

Assessment of plant biodiversity at a mid-elevation evergreen forest of Kalakad–Mundanthurai Tiger Reserve, Western Ghats, India

T. Ganesh, R. Ganesan, M. Soubadra Devy, P. Davidar and K. S. Bawa*

Salim Ali School of Ecology and Environmental Sciences, Pondicherry University, Pondicherry 605 014, India

*Department of Biology, University of Massachusetts, Boston, 100, Morrissey Blvd., Boston 02125, USA

Plant biodiversity of an undisturbed mid-elevation evergreen forest in the southern Western Ghats was assessed by establishing 5 transects totalling 3.82 ha. All plants above 10 cm DBH were enumerated and 10% of the transect area was sampled to quantify the diversity of understorey community and to assess the regeneration status of tree species.

A total of 173 woody plant species from 58 families were recorded; of these 50% were tree species. Species diversity (H') was 4.87, ranking highest among other similar sites in the Western Ghats. On the basis of dominance, this forest is identified as *Cullenia Aglaia Palaquium* type which is considered as a subtype of *Cullenia Mesua Palaquium* series. Stem density and basal area was 363.67 (0.5 ha) and 42.03 m²/ha respectively. The 'L' shaped curve of different DBH classes indicates good regeneration in the climax forest. Small scale altitudinal changes on species composition are largely due to transition in vegetation types influenced by bioclimatic and edaphic factors.

A major impediment in documenting forest vegetation in the country has been the lack of any quantitative information. Forest vegetation has been largely described on the basis of qualitative criteria such as the physiognomy and the dominant species^{1,2}. Quantitative descriptions of vegetation, documenting the relative abundance and distribution of plant species are uncommon. Within the Western Ghats, as elsewhere in the world, species richness is high in the wet evergreen forests. Yet except for Pascal's studies, based on 0.16 to 0.20 ha plots, there is no quantitative assessment of plant biodiversity for an area that covers 28,000 km².

Apart from deforestation, forest degradation is a major problem in Indian forests. Forest Survey of India's latest report shows that 40% of the country's forest has less than 10%–40% of canopy cover³. Regeneration in many of India's forests, including the forest of Western Ghats, is inadequate to replace the adults^{4,5}. Thus in

addition to quantitative assessment of plant biodiversity, we also need to assess the regeneration status of the forest communities.

The present study is based on the mid-elevation evergreen forests in the Agasthyamalai range of the southern Western Ghats. This range has been recognized as one of the five centres of high plant diversity in India by the International Union for Conservation of Nature and Natural Resources⁶ and is well known for its species richness and endemism. The area harbours not less than 2000 plant species out of 3500 species found in Western Ghats⁷.

Previous floristic studies in Kalakad hills have been restricted to botanical explorations^{8–13} until Parthasarathy *et al.*¹⁴ undertook a quantitative study in the Sengaltheri forests in Kalakad–Mundanthurai Tiger Reserve (KMTR). However, this study was done at a lower elevation and in a transition zone between evergreen and semi-evergreen forests, and the wet evergreen forest at a higher elevation was not sampled intensively. Moreover, only large trees were sampled in 1 ha square plots. The present study makes a quantitative assessment of the evergreen forest at a higher elevation in the reserve, and it also includes all plants < 10 cm DBH.

This study is part of an overall project that seeks to assess and monitor biodiversity in the KMTR with the following objectives:

- (i) to assess and describe plant species richness of the wet evergreen forest of Kalakad.
- (ii) to describe the level of spatial heterogeneity in the composition of the forest and
- (iii) to determine if there is adequate regeneration of major tree species.

Study area

KMTR is situated in the Agasthyamalai range of the southern Western Ghats, India, approximately at

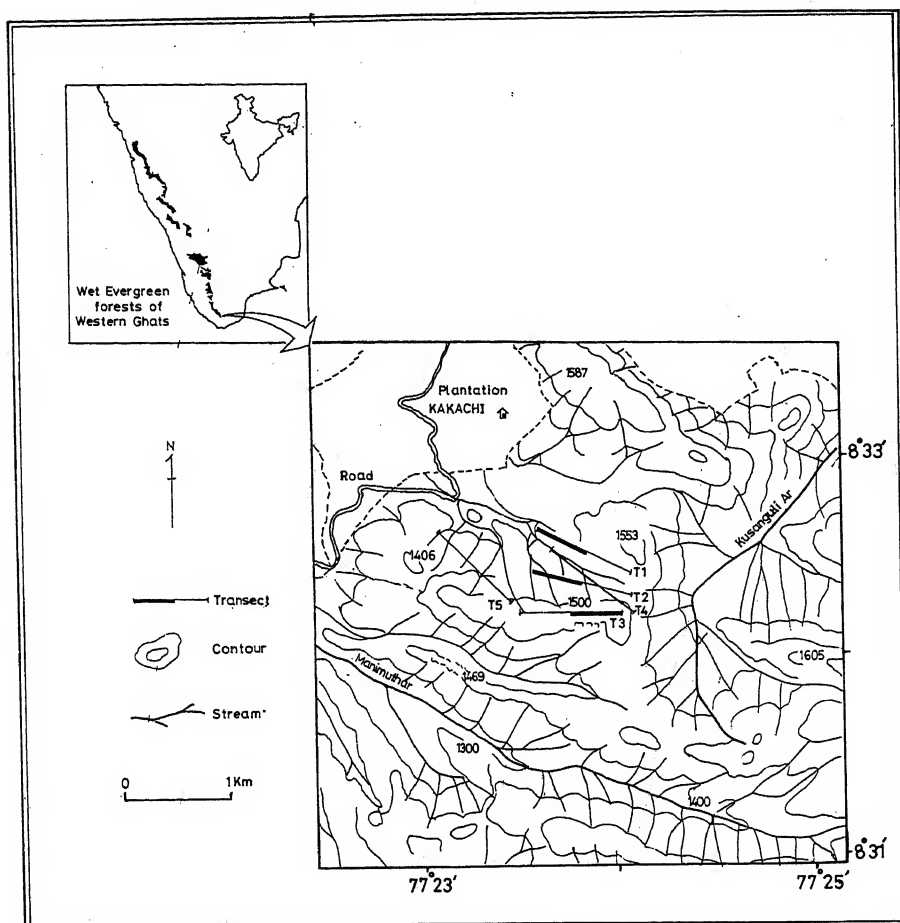

Figure 1. Map of the study area showing location of transects.

77°30'E and 8°40'N (Figure 1). The elevation of the reserve ranges from 100 to 1880 m (Agasthiar peak). The elevation gradient generates a range of vegetation from dry scrub at 150 m to dense evergreen forest above 1000 m. The study site is located near Kakachi (1250 m) in the core area of KMTR on a stretch of gently-undulating terrain, which abruptly increases in gradient forming a ridge facing northeast. The elevation of the ridge ranges from 1200 m at its base to 1550 m at its crest and is covered by dense primary forest interspersed with rock faces and *Ochlandra* facies. These forests are generally classified as belonging to the *Cullenia Mesua Palaquium* series¹⁵. The ridge occupies an area of more than 100 ha and is part of a continuous forest extending over 887 sq km of the KMTR.

The site receives over 3000 mm of rainfall from the SW and NE monsoons and six months of the year receives over 200 mm of rainfall per month (Figure 2). Temperature does not vary much over the seasons. Mean maximum temperature is 24°C and minimum about 16°C. The soil is poor in nutrients (R. Ganesan and N. Parthasarathy, unpublished) and much of the ground

is rocky. Rocky areas occupy a substantial portion of the evergreen forest.

Methods

Vegetation sampling was done along the ridge from May 1992 to September 1993. Transect method was used to sample the vegetation. Five separate transects were laid in the study area (see Figure 1). Ten plots of 10 m × 10 m were established along three 1 km transects at intervals of 100 m resulting in a 0.1 ha sample for each transect. These were laid at 1220 m (T_1), 1300 (T_2) and 1450 m (T_3) altitude respectively, parallel to the ridge. The transects could not be run strictly along the same altitudinal belt because of topographic constraints. Transect 1 (T_1) ranged from 1220 m to 1300 m, T_2 from 1300 to 1400 and T_3 from 1450 to 1550 m. A preliminary analysis of species-area relationship showed that ten 10 m × 10 m plots were not sufficient as species continued to increase linearly with area. Hence it was decided to treat the first 500 m in the above three transects as a belt of 500 m × 10 m.

Figure 2. Mean monthly rainfall recorded at the site.

Two vertical transects of 990 m (T_4) and 940 m (T_5) long were laid descending from 1550 m to 1220 m and roughly bisecting the ridge. They are approximately parallel and 700 m away from each other. These transects could not be of 1 km length as they reached the crest at 990 m and 940 m respectively.

To sample small scale vegetation changes along altitudinal gradients, six plots were laid at intervals of 50 m elevation along the transects T_4 and T_5 . Each of these six plots had 10 subplots of 10 m \times 10 m forming a belt of 10 m \times 100 m plot. These plots were established at approximately 1200 m, 1250 m, 1300 m, 1350 m, 1400 m and 1450 m, resulting in a 0.6 ha sample for each transect. The total area sampled in this study was 3.82 ha.

All woody vegetation above 10 cm DBH at 1.3 m height was enumerated and tagged in 500 \times 10 m² belts in T_1 , T_2 and T_3 . Similarly the entire length of 990 m in T_4 and 940 m in T_5 were enumerated. All woody plants above 1 cm DBH and below 10 cm DBH were enumerated only in the 10 m \times 10 m plots at intervals of 100 m in the T_1 , T_2 and T_3 . Six such plots at intervals of 50 m altitude along T_4 and T_5 were similarly enumerated. Herbs were sampled by randomly laying 1 m² plots in the 10 m \times 10 m plots. Epiphytes were not sampled in this study. Trees and shrubs were included if their centre fell within the plot. Similarly lianas whose base fell inside the plot were enumerated. On uneven terrain, DBH was measured on the side facing the slope. Height was measured using a 2 m scale for shrubs and a pocket clinometer for trees wherever possible and visually estimated elsewhere. Altitude was recorded by a pocket altimeter with a sensitivity of 20 m.

To analyse the vegetation characteristics, two important value indices were calculated, one for species and another for family.

Species Importance Value (SIV) was calculated as follows. $SIV = \text{relative frequency} + \text{relative density} + \text{relative dominance}$.

Relative frequency = (number of plots containing a species \times 100)/sum of frequencies of all species.

Relative density = (number of individuals of a species \times 100)/total number of individuals of all species.

Relative dominance = (basal area of a species \times 100)/total basal area of all species.

The Family Importance Value (FIV) was calculated as mentioned by Keel *et al.*¹⁶. The FIV is given by

$FIV = \text{relative density} + \text{relative diversity} + \text{relative dominance}$.

Relative density = (number of individual of the species \times 100)/total number of individuals in the sample.

Relative diversity = (number of species in the family \times 100)/total number of species in the sample.

Relative dominance = (basal area of the family \times 100)/total basal area in the sample.

For lianas, shrubs and herbs, SIV was calculated by adding the relative density and relative frequency only. Specimens were collected for all species. These samples were identified in the field with the help of Gamble¹⁷ and later counter-checked with the reference material available at MH, Botanical Survey of India, Coimbatore. A reference collection of specimens with flowers/fruits was made and preserved as herbarium material.

Results

Floristics and forest structure

A total of one hundred and seventy three species of plants were recorded from the five transects representing 136 genera and 58 families. Canopy and understorey trees accounted for 90 species in 35 families, shrubs (height < 5m, DBH > 1 cm) 50 species in 17 families, herbs (excluding grasses) 18 species in 14 families and lianas 15 species in 11 families. When the species abundance was represented in octaves and the number of species on an arithmetic scale, the resulting pattern was seen to follow the standard log normal distribution (Figure 3). The best fit curve $S_r = 17e^{-(0.246r)^2}$ followed the observed distribution closely towards the higher end of the scale (chi square = 2.41 $p < 0.01$). At the lower end there were still 7 species which are rare and do not occur in the present sample. Maximum diversity was seen among canopy and understorey trees (Shannon diversity index 4.87).

Trees

Lauraceae, Rubiaceae and Euphorbiaceae were the three most dominant families in terms of species richness in the forest (Figure 4). However FIV index for pooled

Figure 3. Log normal distribution of species abundance (> 10 cm DBH).

Figure 4. Family dominance based on species richness. FIV values are given at the end of each bar.

data from all five transects showed that Euphorbiaceae was the most important family with an FIV value of 36.4 followed by Bombacaceae (28.33) and Lauraceae (26.31) (Figure 4). Euphorbiaceae dominated the understorey and only *Macaranga peltata* and *Mallotus tetracoccus* reached the canopy and subcanopy.

Bombacaceae was represented by only one species – *Cullenia exarillata* but because of its larger DBH and high density, it was the second dominant family. In contrast, Lauraceae and Rubiaceae in spite of their high species richness, do not have high FIV value because of their lower density and lower basal areas. Thirty one families were represented by just one species and only sixteen families had more than 3 species. Lauraceae was dominated by trees (16 out of 18 species) and all of them occur at very low abundance. Among Rubiaceae, except for *Tricalysia apiocarpa* and *Canthium ficiforme*,

Figure 5. Species-area relationship of trees > 10 cm DBH.

all other members were shrubs with less than 10 cm DBH.

The species area curve constructed to determine the adequacy of sampling in the three transects showed that very few species are added after 45 plots (Figure 5). For transect T_1 and T_2 such saturation occurred in less than 40 plots. In T_3 more number of plots were needed for the same. As each transect sampled 5000 m² (0.5 ha) of forest (of fifty 100 m², contiguous plots), it appears that by 4500 m², most of the species found in the patch are encountered.

The 0.5 ha sample from T_1 , T_2 and T_3 was used for comparison between transects. Species diversity was higher in T_3 than T_1 (Table 1). Morisita Horn index (measure of beta diversity) showed 19% similarity between the T_3 and T_1 (Morisita Horn index = 0.1893) but 50% similarity between T_1 and T_2 (Morisita Horn index = 0.5004).

From the SIV values calculated with pooled data, *Cullenia exarillata*, *Aglaia elaeagnoidea* var. *bourdillonii* and *Palaquium ellipticum* emerged as the most important species in the forest (Table 2). *A. elaeagnoidea* had the highest density among them. SIV values are influenced by relative dominance and relative density to various degrees for each species. For large trees like *C. exarillata* and *P. ellipticum*, relative dominance accounted for 70% of the SIV value whereas for *A. elaeagnoidea*, although being abundant, accounted for only 32%, because of its smaller girth.

Palm diversity was very low inside the forest. Only one species, *Bentinckia codapanna* with two saplings was encountered. *Nageia wallichiana* (Podocarpaceae), the only gymnosperm in the forest, had only seven individuals (> 10 cm DBH) from the 2708 stems sampled.

Stem density and basal area are shown in Table 1. The first 10 dominant species in the forest accounted for 65% (1496) of the stems sampled, 31% (744) of these

Table 1. Dominant tree species, stem density, basal area and species diversity of different life-forms in the three horizontal transects of 0.5 ha. Number of species is given in parenthesis

Transect	Dominant tree species	Stem density	Basal area (m ²)	Species diversity*			
				Tree	Shrub	Herb	Liana
1250 m	<i>Cullenia exarillata</i> <i>Palaquium ellipticum</i> <i>Agrostistachys borneensis</i>	358	30.01	3.89 (31)	3.72 (27)	1.76 (4)	–
1300 m	<i>Cullenia exarillata</i> <i>Aglaia elaeagnoidea</i> <i>Agrostistachys borneensis</i>	315	27.43	3.96 (36)	3.07 (19)	2.06 (5)	1.79 (5)
1450 m	<i>Aglaia elaeagnoidea</i> <i>Alseodaphne semicarpifolia</i> <i>Hydnocarpus alpina</i>	418	42.35	4.47 (48)	2.47 (29)	2.96 (9)	2.23 (6)

*Shannon–Wiener diversity index calculated to base 2.

are accounted by the top three species, viz *C. exarillata*, *A. elaeagnoidea* var. *bourdillonii* and *P. ellipticum*.

The DBH distribution from pooled data shows a typical 'L' shaped curve (Figure 6). Though T_1 and T_2 did not differ in their distribution (Kolmogorov–Smirnov test $D = 0.0305$ $p < 0.05$), T_3 differed significantly from T_1 ($D = 0.096$ $p < 0.05$) and T_2 ($D = 0.92$ $p < 0.05$). However the general similarity of the 'L' shaped curve in all the transects indicates the undisturbed nature of the forest stand.

The change in abundance of the dominant species along the elevational gradient at intervals of 50 m is shown in Figures 7a and b. Based on their abundance at different elevations, they were classified into two categories; low elevation and high elevation species.

The low elevation species: *Palaquium ellipticum*, *Cullenia exarillata*, *Myristica dactyloides*, *Epiprinus malloiformis*, *Artocarpus heterophyllus*, *Holigarna nigra* and *Elaeocarpus tuberculatus* were found in both the transects but restricted to elevation < 1300 m with the exception of *E. malloiformis* in transect 5.

The high elevation species: Trees like *Pygeum sisparense*, *Alseodaphne semicarpifolia*, *Memecylon malabaricum* and *Syzygium densiflorum* were restricted to above 1400 m whereas *Hydnocarpus alpina*, *Drypetes longifolia*, *Mastixia arborea* also found elsewhere, occurred at a higher density at this altitude.

Shrubs (1 m–5 m)

Over 50 species of shrubs were encountered in the area, dominated by Rubiaceae 14 spp. (30%) and Acanthaceae 9 spp. (18%). Shrub diversity ($H' = 3.91$) was significantly less than tree diversity ($H' = 4.17$; $t = 20.29$, $df = 2725$ $p < 0.001$). Dominant species were *Nilgirianthus foliosus*, *N. perrottetianus*, *Diotacanthus grandis* and *Agrostistachys indica*. The latter two species were common in all the three transects (Table 2).

Figure 6. Size class distribution of all individuals in the transects.

Elevational changes in diversity showed a decrease from 1250 m (T_1) to 1450 m (T_3) (Table 1). Shrub density at every 50 m altitudinal interval also showed a maximum density at 1250 m.

Herbs (<1 m)

The herb community was not dominated by any single family. Families like Rubiaceae, Euphorbiaceae and Zingiberaceae had 2 to 3 species while others were monospecific. Eighteen species of herbs were recorded. Only *Curculigo orchioides* was common to all transects (Table 2).

Elevational changes in diversity increased from lower to higher elevations (Table 2), while abundance shows a high at 1250 m altitude and a low at 1300 m followed by a steady rise further up. Pteridophytes like ferns were found in greater density in the lower altitudes (T_1 and T_2).

Lianas

The forest was poorly represented by large lianas. Only 15 species of lianas were recorded, of which ten species occurred in the > 10 cm DBH class. These constituted only 1% (25 out of 2733 stems) of the forest stand and all occurred at low densities. The Shannon value was 3.05. *Embelia basaal* was the only common liana with a density of 1.83 per ha. Elevation-wise liana diversity increased from T_2 to T_3 , T_1 at 1200 m did not have any large class liana (Table 1).

Comparison of lifeforms in 1 m² subplots among the three transects showed that herbs and shrubs had greater representation in T_3 . Species richness among trees, lianas, shrubs and herbs, however, did not show any significant differences between them (chi square = 5.475, df = 6, $p < 0.05$).

Tree saplings

Most of the dominant species had good representation in the saplings except *P. ellipticum* which did not have many adults and saplings (Table 3). While 7 species did not have any saplings, 8 species did not have any adults but some of them, *Nothopegia travancorica* and *Neolitsea fischeri* had large number of saplings in the 3000 m² area.

Aglaia elaeagnoidea, *Hydnocarpus alpina* and *Gomphandra coriacea* are the common sapling species found in all the three elevations. Frequency of tree sapling

* SIV values from 5 transects.

distribution showed more resemblance between lower and middle elevation (T_1 and T_2) when compared to higher elevations (T_3) (Table 3). In T_3 , saplings were dominated by *Eugenia maboides*, *Hydnocarpus alpina*, while some dominant species like *Aglaia elaeagnoidea* and *Alseodaphne semecarpifolia* had poor recruitment. In general, understorey growth was dominated by shrubs (2483 per 0.3 ha) and not by tree saplings (562).

Discussion

Species richness

The Western Ghats harbour over 3500 species of flowering plants out of the 17,000 species described from India¹⁸. The Agasthyamalai range in the southern Western Ghats alone includes more than 2000 or 57% of the

3500 species⁷. Of these, 173 or 8.65% occurred in the transects at Kakachi.

The species-area relationship for the horizontal transects shows that by 4500 m² the species accumulation curve saturates for transects at 1200 m and 1300 m. For the transect at 1450 m, it did not saturate and is likely to increase even beyond the 50th plot (0.50 ha). This may be due to the transition in vegetation type at this altitude. The shape of the species area curves obtained at Kakachi was similar to those of Silent valley¹⁵ and Anamalais¹⁹ as most of the species there were also encountered by 0.45–0.5 ha. These cannot be strictly compared because they involve non-contiguous plots separated by long distances. Similar saturation of species area curves between 0.4 and 0.5 ha are also recorded from montane rainforests in South America²⁰. Further, the log normal distribution of species abun-

Table 4. Summary of vegetation studies in the evergreen forests of Western Ghats

Singh *et al.*²² and Pascal¹⁵ considered plants > 10 cm GBH, Parthasarathy *et al.*¹⁴, > 30 cm GBH and others > 10 cm DBH.

dance at Kakachi shows that only 7 species could be encountered with additional sampling. Extensive random search in the area revealed 6 uncommon species which were not encountered in the plots. Therefore it appears that a linear plot of 500 m × 10 m (0.5 ha) is sufficient to estimate the diversity of tree species at Kakachi, provided the elevation and the vegetation type remains the same. This may also be true for other mid-elevation forests of the Western Ghats.

In terms of number of tree species per unit area, Kakachi forests appear to have the highest density. Although we did not sample a sufficiently large contiguous area for the work reported here, our ongoing studies for three 1 ha plots reveal on an average 45 species of >10 cm DBH per hectare. Comparable data from similar undisturbed sites are not available. Studies by Pascal^{15,21} and Singh *et al.*²² in the Western Ghats calculated species richness and diversity at 10 cm GBH (3.3 DBH) or 40 cm GBH (12.7 DBH) which are not on par with the present study (see Table 4). Removal of girth limits also does not allow for comparison because of smaller sampling area of Pascal¹⁵ (0.2 ha) and Singh *et al.*²² (<0.1 ha). When similar comparisons are made with neotropical forests, Kakachi with 45 species per hectare is less species rich than BCI in Panama (176 spp. per ha); Upper Amazonia (155–283 spp. per ha) and La Selva in Costa Rica with 100 spp. from 2 to 4 ha (ref. 23). However it should be noted that all these are low-land rainforest sites having greater richness than montane sites.

Shannon index of diversity (>10 cm DBH) for Kakachi appears to have a higher value than other sites in the Western Ghats such as Anamalais¹⁹, Nelliampathy²⁴ and Sengaltheri, Kalakad¹⁴. Differences in the computations of Shannon index could make comparisons difficult. For instance, the Shannon value at Kakachi calculated to base 'e' is only 3.37 while that to base 2 is 4.87. Magurran²⁵ suggests the use of the latter for all purposes. Further, because of differences in area sampled, lack of uniform plot dimensions and standard girth or diameter classes, it is difficult to compare sites. Overall, Kakachi appears to be the most diverse site of all the wet evergreen forests sampled in the Western Ghats. The possible reasons for high diversity at Kakachi could be the larger area sampled and the linear nature of the transects which better estimates species diversity. Moreover the transition in vegetation type at 1450 m from the tropical wet evergreen to subtropical evergreen forest contributed to higher species richness. Further, bioclimatic and topographic factors like bimodal rainfall regime and relatively steeper slopes at Kakachi compared to other sites could also be a cause for some of the differences in species richness observed.

The vegetation of Kakachi does not fit the classical *Cullenia Mesua Palaquium* series described by Pascal¹⁵.

Attapadi forest of Kerala, which also has a similar dominance of *Cullenia Aglaia* and *Palaquium*, and where *Mesua* also occurs as one amongst the 6 dominant species, is identified as the *Cullenia Mesua Palaquium* series by Pascal¹⁵. In the Kakachi forest *Mesua* does not occur at all and hence can be described as *Cullenia Aglaia Palaquium* type which can be considered as a new subtype of *Cullenia Mesua Palaquium* series. However the *Cullenia Mesua Palaquium* type occurs only at a lower altitude (1000 m), contiguous with the Kakachi forest.

The flora at Kakachi consists of 50.6% tree species (>10 cm DBH), 29.8% shrubs, 10.7% herbs and only 8.9% were lianas. Based on floras, Daniel *et al.*²⁶ have shown that for the Western Ghats in general, herbs (52%) form the dominant component followed by trees (20%) and shrubs (16%). Similar comparison with other sites in Neotropics like BCI, La Selva and Ecuador also reveals domination by herb and shrub community, with less than 25% belonging to trees of >10 cm DBH^{23,27}. The overwhelming dominance of tree flora in Kakachi appears similar to the Manus reserve in Amazonia^{23,28}. This may be because in Kakachi like Manus the epiphytes and herbs were not completely surveyed, which could increase the floristic diversity, thereby reducing the dominance of tree and shrub species.

Stem density and basal area comparisons are again possible only for a few sites as mentioned before where values pertain to 10 cm DBH. Among them, Kakachi with 582.7 stems per ha, has a lower value than sites in Sengaltheri of Kalakad (Table 3) and evergreen forests of Karnataka²⁹. Some sites at Sengaltheri were located in 30-year-old abandoned cardamom plantations which had larger number of small-sized stems leading to higher stem density per unit area¹⁴. Basal area comparison reveals that the values in Kakachi are the lowest among other evergreen forests in the Western Ghats. For sites like Nelliampathy²⁴ and Sengaltheri¹⁴, higher basal area might be due to the differences in the altitude sampled. Both these sites were between 1000 and 1200 m altitude representing very tall and large diameter trees. Species composition also contributes to this difference as some species like *Mangifera indica* and *Bischofia javanica* which are restricted to this altitude have very large girths (>3 m) (personal observation). Exceptionally high basal area recorded in Silent Valley sampled by Singh *et al.*²² (Table 4) may be due to smaller plot size which allows the presence of only one or two large trees¹⁵.

Endemism

The Agastyamalai range is known for high levels of endemism in plant species¹⁰. Of the 2000 species found in Agastyamalai (2000 sq km), roughly 7.5% are localized endemics. At Kakachi, of the total 173 plant spe-

cies found in the transects, 8 (4.62%) were localized endemic and account for 5.33% of the total endemic species in the region. Of these, trees account for 5 (62.5%), shrubs 2 (25%) and lianas 1 (12.5%).

Herbs did not have any endemics. This indicates that trees in the evergreen forest make a substantial contribution to the levels of endemism in this area. Moreover, Pascal²¹ also refers to high levels (43.4%) of endemism among trees and shrubs in the *Cullenia Mesua Palaquium* forest. Much of this can be attributed to the overall prevalence of endemism among tree species in the hill top floras of the Western Ghats³⁰.

Elevational aspects

The effect of small scale altitudinal changes on species richness in the Western Ghats is not well documented. In Kakachi, transects and the subplots demonstrate that species richness increased with elevation. This increase is due to the changes in vegetation type toward the ridge from the wet evergreen forest to a more tropical sub montane forest³¹. Some species such as *Alseodaphne semicarpifolia*, *Xanthophyllum flavescens* and *Syzygium densiflorum* are common only above 1400 m. Many species like *Tricalysia apiocarpa*, *Drypetes longifolia* and *Elaeocarpus munronii* have a more disjunct distribution within the 250 m altitude range. Some species like *Palaquium ellipticum* were restricted to lower elevations and only one half of the tail was sampled in this study. The other half of the distribution occurs below 1200 m which was not sampled. Some of the elevational distribution patterns are probably due to edaphic factors and influence of strong winds especially around the exposed areas and presence of *Ochlandra* spp in the study plot. Some species like *Dimocarpus longon*, *Canarium strictum* and *Heritiera papilio* were rare in the site because their optimal habitats occur at lower elevations where they are common. More sampling from lower elevations is required to determine the complete elevational ranges of these species.

Regeneration

Though many forests in the Western Ghats are reported to have poor regeneration^{4,5}, the first five dominant species at Kakachi show adequate regeneration ranging from 7 to 135 individuals per 0.1 ha at the 1 to 10 cm DBH levels. Similarly in BCI it ranged from 4 to 47 individuals per 0.1 ha of the most abundant tree species³². However low density species like *Syzygium mundagam* and species with large diameter classes like *Calophyllum austroindicum* did not have many saplings in the plots. These species also suffer very high mortality at the seed stage from vertebrate seed predators³³.

Such high predation could have depressed their recruitment. Regeneration in such species could also be episodic.

Conclusion

The wet evergreen forests of Kakachi show a high level of plant species diversity compared with the other evergreen formations in the Western Ghats. It also shows good regeneration relative to many dry forests in India.

Comparative analysis with other sites in the Western Ghats was severely hindered due to lack of any standard protocol in sampling vegetation. Future studies should follow certain norms of standardized sampling which could be readily used across sites for easy comparison. This is very important for sites which will be used for monitoring vegetation dynamics.

Even though this medium elevation forest is one of the least disturbed sites in the Western Ghats, its biodiversity is threatened due to fragmentation of climax forest. Fragmentation has resulted from anthropogenic pressures like tea and cardamom plantations and other developmental projects like dams and reservoirs. Though the KMTR is spread over 887 sq km, the evergreen forests are restricted to a much smaller area at the medium elevations which are also the preferred sites for tea, coffee and cardamom plantations. Further, these forests in the Agasthyamalai hills serve as watershed areas for many major perennial rivers like Tambaraparani, Manimuthar, Kodayar and Pachaiyar which are the main water source for the southern districts of Tamil Nadu. Thus preservation of these forests is crucial not only for maintaining the biodiversity, but also for meeting the basic needs of the human populations in the plains.

ACKNOWLEDGEMENTS. This paper represents contribution number 38 of a research programme in conservation of biodiversity and the environment jointly coordinated by Tata Energy Research Institute and the University of Massachusetts at Boston. The programme is supported in part by the Mac Arthur Foundation. We thank the Tamil Nadu Forest Department for permission to conduct this study and the Tamil Nadu Electricity Board at Kodayar for logistic support. We acknowledge the help of the Deputy Director, BSI (SC), Coimbatore for identification of plants. Dr K. S. Murali, Dr B. R. Ramesh and an anonymous reviewer provided valuable comments on the ms. Field support came from various people. Among them we thank Ananthanarayan, Rani Krishnan, Aditi Sinha and Raja.

Managing the impact of seasonal rainfall variability through response farming at a semi-arid tropical location

U. S. Victor, N. N. Srivastava, A. V. M. Subba Rao and B. V. Ramana Rao

Central Research Institute for Dryland Agriculture, Hyderabad 500 059, India

A method of Response Farming Programme for managing risks associated with variable seasonal rainfall was developed for a semi-arid location using daily rainfall records for the period 1971-94. The risks are intense rains threatening soil erosion, prolonged heavy rains threatening water logging, prolonged low rainfall periods, early cessation of rains long before the maturity of crops and too little rainfall in relation to crop water requirements. Onset relations, i.e. relations between season rainfall parameters (amount, duration and average rainfall per day) and date of onset of the rainy season are determined. It has been demonstrated how these relationships can be used in the selection of crops/cropping systems, fertilizer application rates, plant population, etc.

In rainfed agriculture, farmers must cope with rainfall variability both within and between seasons. If rainfall

were uniform every year, farmers would choose a single management plan. Crops, planting date, seeding rate, fertilizer and insecticide would be planned for that anticipated single rainfall pattern. Obviously, this is not the case and variability of rainfall creates major problems. Response Farming is a means of coping with this seasonal rainfall variability which provides a method of identifying and quantifying seasonal rainfall variability and its related risks and of addressing the latter at the farm level. This is accomplished through improved prediction of expected rainfall behaviour in the approaching cropping season enabling improved decisions at the field level. The date of onset acts as a rainfall (amount, duration, average rainfall per day) predictor for the remainder of the season. Current rainfall is used to determine the management strategies which are responsive to the weather patterns. Stewart¹ developed Response Farming Strategies by studying the relationship between

onset of the rainy season versus duration of the rainy season and onset versus rainfall amount during the rainy season for two locations, Niamey and Bouza. In order to assess the rainy season potential for crop growth, Siva Kumar² has determined the relationship between duration and onset for 58 locations in the Sahelian and Sudanian Zones of Niger and Burkina Faso. In the present study, two types of analysis were done. The first analysis provides a general characterization of historical rainfall behaviour for purposes of determining cropping potential in new development areas or presently farmed lands. Analysis two simulates historical water supply conditions for crops of specified types and maturities. This type of analysis assumes that final decisions are based on date of onset but the effective cropping season begins at germination.

Materials and methods

The daily rainfall data for the period 1971–94 recorded at Hayatnagar Research Farm of Central Research Institute for Dryland Agriculture (CRIDA), Hyderabad (17°27'N, 78°28'E) were utilized in the present study. The farm situation represents semi-arid tropical region of Peninsular India, with an average annual rainfall of 733 mm and potential evapotranspiration of 1754 mm. Nearly 70% of the total precipitation is received during the southwest monsoon season (June to September). Post-monsoon rains are not uncommon and occur around 18% of average annual rainfall. The monthly normal potential evapotranspiration values given by Rao *et al.*³ were utilized in the present study.

Soils of the experimental site are shallow alfisols. Moisture storage in the profile is only 24% by volume and permanent wilting point is 14% by volume. The soils are low in nitrogen and extremely low in phosphorus. The yields of sorghum (CSH-6), pearl millet (BJ-104), castor (Aruna), pigeonpea (HY-2) and sunflower (68415) were simulated (1971–94) using the water production functions developed by Victor *et al.*⁴

The following assumptions were made to identify beginning, end and duration of the rainy season to characterize the rainy season behaviour^{5,6}. The date of onset of rains is defined as that date after 28 May, when rainfall accumulated over two consecutive days is at least 20 mm. The date of ending of the rains is taken as that date after 1 September following which no rainfall occurs over a period of 30 days. The duration of the rainy season is taken as the difference between beginning and ending of rainy season. Frequency distribution of dates of beginning and ending of the rains and duration of the rainy season were estimated by fitting a normal distribution. Then the probabilities for different durations of the rainy season for early, normal and delayed onset of rains were obtained.

A computer-based Response Farming Programme which incorporates a bare soil water balance algorithm⁷ was developed to simulate historical water supply conditions based on which the date of onset, germination and duration of the crop growing season were identified. The following are the inputs to this analytical programme.

- Daily rainfall (mm).
- Mean monthly potential evapotranspiration (PET) (mm).
- Daily PET values were calculated/assumed as follows^{8,9}:

$$\text{PET} = (\text{Mean monthly PET}) * 1.1/30$$
 on days with no rainfall
 4 mm/day on days with 1–10 mm rainfall
 3 mm/day on days with 11–20 mm rainfall
 2 mm/day on days with > 20 mm rainfall.
- Field capacity of the soils of the experimental site is 0.24 by volume.
- Permanent wilting point is 0.14 by volume.
- Air dry water content is 0.04 by volume.
- 1 May to begin search.
- First accepted date of onset for cropping, 1 June.
- *Onset criterion*: 20 mm of stored water in the 30 cm soil profile from the new rains. Evaporation assumed to continue throughout the soil–water accumulation process. Losses to runoff assumed zero.
- Planting to begin after a minimum delay of three days provided the rainfall is less than 5 mm/day.
- *Germination criterion*: 15 mm of water stored in the 30 cm soil profile to effect germination. Usually occurring on the first day following planting.
- Last search date for season end rains is the crop maturity date.
- *Final rain date criterion* is to sum rainfall backward from the maturity date to accumulate 50 mm, then proceed forward toward the maturity date until average daily rainfall fell below 2.5 mm/day.

The analysis was done for 90, 100 and 150 days maturity crops which corresponds to sorghum [(CSH-6) and pearl millet (BJ-104)], sunflower (68415) and [pigeonpea (HY-2) and castor (Aruna)] respectively.

Results and discussion

General characterization of rainy season behaviour

Quantification of risks due to variable seasonal rainfall. The following risks, viz. (a) rainfall intensity, (b) prolonged heavy rainfall periods, (c) prolonged low rainfall periods were quantified. The following conclusions were drawn from the analysis.

Intense rains threatening erosion of the basic soil resource: Based on the frequency distribution of daily rainfall data, the chance of occurrence of 75 mm or

RESEARCH ARTICLES

more is very low (0.5%) and the probability of getting the rainfall in the range 50–75 mm per day is only 0.3%. However, the occurrence of low rainfall amounts (<25 mm/day) is very high (98%). Considering the analysis for shallow alfisol, it was judged that the erosion hazard in the present rainfall circumstances is moderate.

Prolonged wet and dry spells: A first order Markov chain probability model was fitted to daily rainfall data to calculate initial and conditional probabilities for two rainfall limits (2.5 mm and 10 mm)^{10,11}. Using these probabilities of dry and wet spells and, conditional dry spells, which is the length of a dry spell conditional on the day prior to the beginning of the period being rainy, were calculated and are given in Table 1. These data are presented from 3rd week of May to last week of October (21–44 standard meteorological weeks) which is the period during which rains are received. These data provide quick overview of risks due to dry spells during the rainy season.

It is evident from the analysis that wet spells in the current cropping season exceeding 10 mm per day continuously for five days or more in a week are infrequent (<1%). It is seen from Table 1 that mid-season dry spell during August (32–35 weeks) exceeding five days is in the range of 16–35%. The conditional dry spell length five days during 23–26 week is in the range of 12–25%. However, if the onset is earlier than 23rd

week, the probability of getting conditional dry spell of five days increases (more than 46%), which indicates that sowing field crops with first rains before 23rd week is fraught with considerable risk while the period after 23rd week is slightly favourable since the probability of dry spell decreases rapidly, indicating significantly reduced risks to the emergence and subsequent growth of crops.

Relationship between date of onset and rainfall amount and date of onset and rainy season duration. Seasonal rainfall amount, duration and average rainfall per day are linked to the date of onset. For predictive purposes, onset was divided into three distinctive time periods, viz. early (May 28–June 10), middle (June 11–30), and late (July 1 onwards).

Table 2 shows the median values of monsoon rainfall attributes at Hayatnagar Research Farm for the entire 24-year record studied and then for each of the three groupings of seasons defined by the prediction criteria outlined above. It is evident from Table 2 that over all median cropping season rainfall of 581 mm persisting 150 days with an average rainfall of 4.5 mm per day. Seasons with early onset show higher rainfall amount, longer duration and higher average rainfall per day. Seasons with middle period onset have lower rainfall, same duration and less average rainfall per day. Late onset seasons have the least rainfall and shortest durations, but paradoxically the highest average rainfall per day of all. The importance of the differences among the predicted groupings in Table 2 is more easily grasped when ranges of values within each of the categories are seen in addition to the median values. Table 3 presents the ranges, starting with the 24-year record as if no predictions were involved. Rainfall amount ranged from low of 327 mm to a high of 1077 mm. Duration is 79 to 167 days and average rainfall per day is as low as 2.2 mm per day and as high as 6.8 mm per day. If the onset is early (by June 10), the rainfall was never less than 395 mm but fell to 327 mm with middle period onset and to 448 mm in the late seasons. Similarly, duration never fell below 120 days for the early onset seasons and decreased to 92 days for middle period onset and 79 days for late onset seasons. The average rainfall per day for the early and middle onset periods ranges from 2.2 to 6.8 mm per day. However, the late onset seasons show high average rainfall per day.

Selecting crops/cultivars and cropping systems based on predicted duration. Actually, crop/cultivar selection based on predicted duration requires consideration of (a) length of growing season (maturities) of different crops and cultivars in the planning site environment, (b) rapidity of planting (no. of days it takes to plant following onset), (c) soil depth and water-holding

*Calculation of dry spell conditional on the day before the start of the period under consideration being rainy.

capacity, (d) crop coefficients for the estimation of water requirements, and (e) evaporative rates through the season.

The goal of planning exercise is to select crop/cultivars that will reach maturity within the rainy period or within a time period following the final rain date but before completely running out of extractable soil water.

For example, from the data in Table 4, it is seen that in 38% of years only more than 150 days duration is possible if the onset is normal. However, this length of the season does not support sequence cropping even with short duration crops and varieties as the soil has low water-holding capacity. The long duration crops like castor or pigeonpea occupy complete growing season. Any intercrop reduces the yield of castor. With short duration cereal crops like sorghum and pearl millet, quite a good length of growing season is left unutilized. Therefore intercropping of sorghum/or pearl millet with pigeonpea is the best system suited for this region.

Characterization of rainy season behaviour with reference to specific crops. The analysis was done for 90, 100 and 150-day crops. The relationship between rainy period duration and date of onset, average crop season rainfall and date of onset, and total rainfall in 30 days after germination and date of onset are presented for

sorghum and castor in Figures 1 and 2. The following important conclusions can be drawn from these figures.

Rainfall duration of 80 and 110 days or more is sufficient to permit a 90 and 150 days sorghum and castor cultivars respectively to produce yields greater than 75% of the maximum. Both sorghum and castor can be seeded till the end of July. However, if sorghum is seeded beyond June, its yields will be reduced drastically due to shootfly attack. As an alternative, pearl millet can be seeded up to mid-July. With later seedings, this crop matures in cool weather and results in ergot infection. Under delayed seeding conditions up to the end of August, minor millets like finger millet, foxtail millet can be seeded. As a last chance horsegram can be seeded up to the end of September.

Following determinations of cultivar maturities to be grown, the next selection is type of crops themselves. This is done by relating average season rainfall to daily water requirements of crops of interest. Average season rainfall per day is calculated by dividing the total season rainfall by the maturity of the crop. For example, for sorghum, it is seen from Figure 1 b that average season rainfall per day ranges from just above 1.9 mm per day to just below 8.0 mm/day. Season water supply averaging at or above 5 mm/day should be capable of producing yields greater than 75% of maximum provided the

the average daily water supply falls to about 4 mm after which subsistence level production is expected (50–25% of the maximum yields). When the daily water supply falls below 2 mm, the yields less than 25% of the maximum can be expected.

The relationship between total rainfall in the next 30 days after germination and date of onset enables the farmers to take decisions for the second time in deciding fertilizer rates and plant population. Here, it is assumed that water supply up to 30 days after germination is adequate to provide low risk guidance on whether to add fertilizer for high rainfall conditions or to thin and reduce the plant populations for low rainfall conditions. For example, it is evident from Figure 1 c that if total rainfall in 30 days after germination exceeds 100 mm, sorghum yields greater than 75% of the maximum can

Sorghum Yields: ■ >75% + 75-50% * 50-25% □ <25%

Castor Yields: ■ >75% + 75-50% * 50-25% □ <25%

Figure 1 a-c. a, Relationship between rainy period duration and date of onset at Hayatnagar; b, Relationship between average crop season rainfall and date of onset at Hayatnagar; c, Relationship between total rainfall in the next 30 days and date of onset at Hayatnagar.

Figure 2 a-c. a, Relationship between rainy period duration and date of onset at Hayatnagar; b, Relationship between average crop season rainfall and date of onset at Hayatnagar; c, Relationship between rainfall in the next 30 days and date of onset at Hayatnagar.

be expected. Therefore, if water supply in 30 days after germination exceeds 100 mm, apply fertilizers and if less than 100 mm, reduce the plant population by thinning and leave the fertilizer as before. Actually the 30 day water supply in most years is far above the 100 mm minimum which signals yields greater than 75% of the maximum. This means that the 100 mm rainfall is often reached long before the 30 days have passed. The decision, therefore, for additional nitrogen fertilizer can usually be made well before the action must be taken, thus extending preparation time. The predictive criteria, decisions and recommended actions suggested in this paper are not definitive. These are yet to be tested at field level before using them for operational purpose.

Conclusions

Seasonal variation in rainfall poses the greatest climatic risks to agricultural production in rainfed farming areas. In the variable rainfall zones at least five aspects of seasonal rainfall behaviour need to be evaluated in terms of agricultural production. These are intense rains threatening erosion, prolonged heavy rains threatening water logging, prolonged low rainfall periods within the cropping season, early cessation of rains too long before crop maturity or too little rainfall in relation to crop water requirements. A number of relationships between the onset of cropping season rainfall and such farm relevant rainfall parameters, such as rainfall amount, duration and average rainfall per day are determined by analysing the historical rainfall records. cursory examination of the rainfall data indicates that risk from prolonged heavy rains is not much, particularly on shallow alfisols. But spells of dryness or exceedingly low rainfall do pose risk during the cropping season. Duration is very much correlated with date of onset of the rainy season, hence is the key factor in selecting maturities of crops/cultivars and cropping systems to be grown. Relating duration to onset dates provides season-by-season guidance. Following determination of cultivar maturities to be grown, the next selection is the type of crops themselves. This is done by relating

average water supply per day to daily water requirements of crops of interest. The crux of the management problem with variable rainfall condition is to adopt soil fertility and plant populations to actual rainfall conditions in the season at hand. Fortunately farmers can delay final decisions on these questions until about 30 days after germination. In the case of sorghum if water supply in 30 days after germination exceeds 100 mm, apply fertilizer and if less than 100 mm, reduce plant population by thinning and leave fertilizer as before.

Ultrasonic agitation of Kevlar fibres

R. V. Iyer and Kalyani Vijayan

Materials Science Division, National Aerospace Laboratories,
Bangalore 560 017, India

Kevlar 49 fibres exposed to ultrasonic waves suffer axial compression manifested by the introduction of kink bands, dispersion of fibrils and macrobuckling. Application of subsequent tensile load, however, influences the kink bands.

In polymer research, ultrasonic waves are traditionally used for the study of dynamic processes such as polymerization and degradation. Nondestructive testing of resins with ultrasonic waves is also well known. Reviews describing different types of studies on polymeric materials employing ultrasonic waves are available^{1,2}. In this communication we present details of some observations concerning the residual effects of exposure to ultrasonic waves on the aramid fibre Kevlar.

A bundle of Kevlar 49 fibres (approximately 150 mm long and 2 mm thick) made commercially available by DuPont Inc. USA, was exposed to ultrasonic waves of frequency 40 ± 3 kHz generated by a fully transistorized ultrasonic generator. Distilled water was used as the transmitting medium. Figure 1 is a schematic representation of the experimental arrangement used. The generator and the tank containing the sample were coaxially connected. Fibres were subjected to cumulative exposure to ultrasonic waves for 1, 3 and 6 h respectively. The choice of the time intervals was purely arbitrary. In the course of the agitation, the distilled water surrounding the sample was getting heated, the temperature rising to $\approx 40^\circ\text{C}$ after ≈ 2 h of agitation. At such stages, the agitation was disrupted and continued further only after the liquid returned to the ambient temperature of $\approx 25^\circ\text{C}$. Surface characteristics of ultrasonically agitated filaments were subsequently examined in an optical microscope using polarized light in the reflection geometry.

The most conspicuous effect of ultrasonic agitation on Kevlar fibres is the introduction of kink bands. Figure 2 compares the surface characteristics of Kevlar fibres both prior to and after ultrasonic agitation. Fibres agitated for 1 h include isolated, faint kink bands which are either normal or inclined to the fibre axis. In contrast, fibres agitated for 3 and 6 h exhibit a concentration of V- and X-shaped bands which are distinctly darker and more in number than the bands found in fibres agitated for 1 h. The V- and X-shaped bands are found almost continuously along the length of the agitated fibre. Kink bands, as is well known, correspond to structural deformation³. The bands which are inclined to the fibre length are attributed⁴ to tangential deformation of the

radially oriented molecular architecture⁵ which characterizes Kevlar fibres and the perpendicular bands are correlated with radial splitting of the fibrils⁴. The V- and the X-shaped features represent multiple bands and they result from overlapping inclined and normal kink bands. The surface characteristics of Kevlar thus indicate that exposure to ultrasonic waves introduces structural deformations which in turn lead to the formation of kink bands and the severity of the deformation increases with increase in the duration of exposure.

Ultrasonic agitation is also found to cause dispersion of fibrils (Figure 3 a). The separated fibrils tend to get entangled around the main fibre with subsequent agitation (Figure 3 b). Figure 3 c shows another feature, viz. the macrobuckling. Along the length of the agitated fibre, notch-like regions of the type shown in Figure 3 c where fibre changes direction or buckles, have been observed. Conspicuously, the macrobuckling is less rampant than the formation of kink bands and also the dispersion of fibrils.

It must be pointed out that the formation of kink bands, separation of fibrils and macrobuckling are characteristics typical of axial compression of Kevlar fibres⁶⁻⁸. The remarkable similarity between the characteristics of the ultrasonically agitated and the axially compressed Kevlar fibres suggests that exposure to ultrasonic agitation causes axial compression. Occurrence of such axial compression is not surprising because the fibres were positionally unconstrained during the process of ultrasonic agitation. It is not unlikely that at some point of time they got favourably oriented to suffer axial compression by the continuously impinging ultrasonic waves.

The kink bands, both single as well as multiple, formed by ultrasonic agitation of Kevlar are found to be sensitive to subsequent tensile loading. The effect of tensile loading was followed by using a spring loaded

Figure 1. Schematic representation of the arrangement used for ultrasonic agitation.

Figure 2 a-c. *a*, Surface of the $\approx 11\ \mu\text{m}$ thin fibre prior to ultrasonic agitation; *b* and *c*, V- and X-shaped kink bands in fibres agitated for 3 and 6 h respectively.

device of the type shown in Figure 4. In this device the fibre held taut between the two sets of screws could be stretched to different extents by adjusting the lead screw, S. It was found that with increase in the extent of stretching, the kink bands on the surface of the fibre turned progressively less intense and eventually, at some stage of stretching, the kink bands were not observable. It must be emphasized that on releasing the tensile load on the fibre, the kink bands did not reappear. These observations suggest that the structural deformations which led to the occurrence of kink bands are not permanent and the severity of these deformations could be lessened or removed with subsequent application of tensile load to the fibre. In order to test whether the kink bands which characterize fibres compressed by the recoil method⁸ also exhibit a similar behaviour, optical examination under the application of tensile load was extended to Kevlar fibres compressed by the recoil method. Interestingly, irrespective of the method of formation, under the application of tensile load, the kink

Figure 3 a-c. *a*, Dispersion of fibrils; *b*, Dispersed fibrils coil round the fibre; *c*, Macrobuckling of the fibre.

bands behaved in an identical fashion, viz. disappeared with the application of load. Figure 5 illustrates an example of the effect of stretching on kink bands. It must be pointed out that these observations pertain only to the surface of the fibre. Information on the effect of tensile load on ultrasonically induced deformations residing away from the surface and towards the core of the fibre is not available at the present moment. TEM observations are likely to provide insight into this aspect. It must be mentioned that in the present study, the stretching which the fibres were subjected to was not quantified. Consequently, calculations providing correlation between the tensile load and the energy needed for the removal of the deformation which caused the kink bands were not possible.

Figure 4. Device used for stretching the fibre.

In contrast with the kink bands, the macrobuckling introduced by ultrasonic agitation is not removed by subsequent stretching. The notch-like regions (Figure 3 c) representing change in direction thus appear to represent comparatively more severe and irreversible structural deformations introduced during ultrasonic agitation.

It must be mentioned that Allen and Roche⁹ have observed a similar effect of tensile load on Kevlar fibres. Their observations indicate that the pleated structure¹⁰ which characterizes Kevlar gets straightened with the application of tensile load. However, in contrast with the kink bands, the pleats reappear with the removal of the load.

Spontaneous regeneration of pancreatic β -cells in EMC-D virus-induced diabetic mice and reversion from diabetic to normal state

R. R. Bhonde

National Centre for Cell Science, 'Jopasana', 85/1, Paud Road, Kothrud, Pune 411 029, India

With an aim of developing a model of experimental diabetes by which spontaneous recovery and regeneration processes can be investigated, EMC-D virus-induced diabetic mice were used as a system to study regeneration *in vivo*. Ninety per cent of the EMC-D virus-inoculated mice developed diabetes within a week after inoculation as judged by the glucose levels in blood and urine. Fifty-five per cent of the diabetic mice died within a fortnight after virus inoculation. Thirty per cent of the total infected mice slowly recovered from the diabetic state as evidenced by diminishing glycosuria, hyperglycaemia and near normal histological architecture. The results indicate reversion from clinical diabetes to normal status. Thus EMC-D virus-induced diabetes in SJL/J mice provides a new model to investigate mechanism and factors involved in regeneration of pancreatic β -cells *in vivo*.

INSULIN-dependent (Type 1) diabetes mellitus is an autoimmune disease caused by the selective destruction of islet β -cells, and the arrest of their regeneration potential may lead to a total disappearance of the cells. At the onset of diabetes about 80–90% of the β -cells are destroyed, resulting in severe hyperglycaemia¹. Recently, it has been shown that viable and insulin-producing β -cells are present in human pancreatic islets at the onset of Type 1 diabetes². It is not known how the β -cells can be triggered to proliferate in response to a moderate loss, providing that the residual β -cell mass is sufficient to maintain the glucose homeostasis under the condition where the glucose tolerance is already impaired³. Few cases of spontaneous and long lasting recovery from severe insulin-dependent diabetes mellitus in human and from drug-induced diabetes in animals are known^{4,5}. It is not known whether β -cells in human beings regenerate. Since it is difficult to estimate regenerating β -cells in human cases of diabetes, it was thought worthwhile to use animal models of diabetes for this purpose. In the murine model of virus induced, insulin-dependent diabetes mellitus (IDDM), it has been shown that D-variant of EMC virus infects and lyses pancreatic β -cells⁶. The severity of diabetes is related to the extent of β -cell damage⁷. The earlier work on EMC-D induced diabetes in mice pointed out survival of diabetic mice for several days after virus infection, exhibiting abnormal glucose tolerance^{6,8–10}.

However, detailed clinical and histological studies of the surviving population were not carried out. Hence, the present study was designed to ascertain whether EMC-D virus-induced diabetic mice exhibit regeneration potential and eventual reversal of diabetes.

The D variant of EMC virus (plaque purified from mouse heart passaged M variant) was used in all the experiments. The source and preparation of EMC-D virus are described earlier⁶. Virus pools were prepared from L929 cells, and the virus titre was determined by plaque assay on L929 cells¹¹.

Male SJL/J mice were obtained from the Jackson Laboratory, Bar Harbor, Maine and housed in the animal facility in the Health Sciences Centre, University of Calgary, Calgary, Alberta, Canada. Except when noted, 5-week-old mice were used. A total of 60 mice were divided into 2 groups, control group of 20 mice and experimental group of 40 mice respectively. EMC-D virus was injected intraperitoneally into the experimental group (with 0.2 ml/mouse containing 100–500 p.f.u.). The control group was inoculated with 0.2 ml of phosphate buffered saline (pH 7.2).

Beginning 3 days after infection with virus, glucose levels in the urine were measured every alternate day with Diastix (Ames Division, Miles Laboratories Ltd., Etobicoke, Ontario, Canada). Blood glucose levels were measured in blood from the retro-orbital venous plexus by use of glucose oxidase assay with *o*-dianisidine dihydrochloride as the indicator dye⁶. Nonfasting glucose levels in the blood were measured on 5, 10, 15, 20, 25, 35 and 45 days after infection. The mean nonfasting glucose level of 20 uninoculated SJL/J male mice was 158 ± 19 mg/dl. In these experiments, any mouse with nonfasting glucose level greater than 215 mg/dl (3 standard deviations (SD) above the mean) was scored as diabetic.

Insulin was extracted from pancreas of mice sacrificed on 5, 20 and 45 days after infection by acid ethanol method¹² and the insulin content of the pancreatic extract was measured by RIA¹³ and expressed as μ g/g of pancreas. Briefly, pancreas were disintegrated by ultrasonic procedure at 4°C in 0.5 ml acid-alcohol solution (75% ethanol and 1.5% 10 N HCl v/v). The homogenates were kept at -20°C until insulin was assayed by RIA.

At 5, 20 and 45 days after virus inoculation, several mice from control and experimental group were sacrificed and the pancreas were fixed in Bouin's fixative. Paraffin-embedded sections were stained with haematoxylin and eosin and examined to score presence or absence of insulinitis and normal islet morphology.

Data obtained are summarized in Tables 1–3. Table 1 shows the glucose levels of blood and urine at various days after virus inoculation and the incidence of diabetes in the 2 groups. Animals in the control group did not show signs of development of diabetes throughout the

RESEARCH COMMUNICATIONS

period of observation as indicated by absence of glucose in urine and blood glucose levels < 200 mg/dl at all the time points noted. However, in EMC-D virus inoculated group 36 out of 40 mice (90%) became diabetic within a week after virus inoculation, as revealed by the presence of glycosuria and hyperglycaemia (blood glu-

cose > 450 mg/dl) which persisted for about 20–25 days post inoculation. A large number of mice in the experimental group died (20 out of 36) within 2 weeks post-inoculation. In the surviving mice, 75% (12 out of 16) of the mice exhibited signs of reversal of diabetes as revealed by decreasing levels of glucose in the urine and blood. The process of reversal of clinical diabetes began in the 3rd week post-inoculation and was completed after 6 weeks, as evidenced by the absence of glucose in urine and establishment of normoglycaemia (Table 1). In the remaining 25% of the population amongst the surviving mice in the experimental group, blood and urine glucose did not disappear, indicating continued diabetic status.

The reversal of clinical diabetes in the experimental group was further documented by the increase in total weight and insulin content of the pancreas (Tables 2 and 3). It is clear from Table 2 that on day 20 post-inoculation the weight of the pancreas in uninoculated control group (159.0 ± 10.57 mg) is comparable to that of regenerating mice (170 ± 4.0 mg) whereas it is significantly lower in diabetic mice (71.5 ± 7.26 mg). Similarly, there was a significant difference in the insulin content of the pancreas in the control and experimental group of mice on day 5 post-inoculation (Table 3) whereas on day 45 post-inoculation insulin content of pancreas was comparable in both the groups (Table 3), indicating regeneration of islets and documenting reversal of diabetes as revealed by clinical picture. The histopathological studies were carried out on pancreas of control and experimental group at day 5 and day 45 post-inoculation. Figure 1 shows normal histological architecture, islet morphology in control group, whereas Figure 2 shows loss of islet morphology, β -cell lysis and insulinitis in experimental group on day 5 post-inoculation. However, histological picture of experi-

Figure 1. H&E stained section of pancreas from control mouse, showing normal islet surrounded by acinar cells ($\times 320$).

mental group pancreas on day 45 post-inoculation was comparable to that of control group of pancreas on day 45 except for smaller islets in the former (Figure 3).

It is shown in this study that a single injection of EMC-D virus can induce diabetes in SJL/J male mice within a week after virus inoculation by reducing the β -cell mass and insulin content of the pancreas. However, the remaining β -cell volume seems to be sufficient to regain normoglycaemia in at least 30% of the animals (12 out of 40). Taking into consideration the course and outcome of diabetes in the experimental group over a period of time it is seen that there are definite signs of reversal of diabetes as evidenced by the absence of glycosuria, achieving normoglycaemia and insulin content of the pancreas comparable to those of control group. The experimental data indicates reversion of EMC-D virus-induced diabetes. Such type of reversion from diabetic to nondiabetic status has not been reported previously in the case of EMC virus-induced diabetes. The reversal of diabetes obtained in the present study appears to be a case of spontaneous regeneration of the residual β -cell mass that was left intact after EMC-D virus infection. Thus, EMC-D virus-induced diabetes in SJL/J mice provides a new model to study the process of regeneration in pancreatic β -cells and reversal of diabetes. Such a type of spontaneous regeneration has been reported in streptozotocin (STZ)-induced diabetes in mice⁵, which provides another model to investigate mechanisms and promoting factors of such restorative processes. However, the present model differs from STZ-induced diabetic model⁵ in many respects. Firstly, our model involves adult mice as opposed to neonatal mice in STZ model. Secondly, the time of onset and the time of recovery are much earlier compared to the STZ model. The only limitation is the high mortality

rate in our model (55%) as opposed to STZ model. It is remarkable that the mice were able to recover in spite of severe hyperglycaemia, considering the fact that high blood glucose levels *per se* may have toxic effects on pancreatic β -cells⁸. This model also differs from other models of pancreatic regeneration such as partial pancreatectomy⁹ wherein there is 60–90% loss of whole pancreas, which results into regeneration of entire pancreatic tissue as opposed to selective loss and regeneration of only islet tissue as observed in the present study. The EMC-D induced diabetes model also differs from autoimmune models of diabetes such as biobreeding rat¹⁰ and nonobese diabetic mouse¹¹, wherein total destruction of β -cells occurs due to immune cytolytic process, thereby reducing the amount of residual β -cell mass and eventually reducing the chances of regeneration and recovery. It seems plausible to control the degree of damage of β -cells in the present model by reducing the dose of virus injected or by suppressing virus replication¹². Although the present study neither permits elucidation of mechanisms involved in the process of regeneration nor indicates origin of newly developed islets, the results obtained reflect an intrinsic limited capacity or potential of β -cell regeneration. Probably the recovery process might be caused by factors released from damaged β -cells, a mechanism observed in many other tissues after cell damage¹³. Since the number of functionally intact islets is of decisive importance for the development, course and outcome of diabetes, there is very little hope of recovery and regeneration of β -cells in insulin-dependent (Type 1) diabetes which is a consequence of progressive β -cell destruction^{14,15}. However, the recent report² on human pancreatic islet function at the onset of Type 1 diabetes clearly indicates the presence of insulin producing viable cells, suggesting a new

Figure 2. H&E stained section of mouse pancreas, 5 days after EMC-D virus infection showing extensive inflammatory infiltrate with mononuclear cells in the islets of Langerhans ($\times 320$).

Figure 3. H&E stained section from regenerated mouse pancreas on day 45 exhibiting normal islet morphology comparable to that of the control group ($\times 320$).

dimension in the treatment of Type 1 diabetes. In this context, the results of the present study are of importance as they reflect on the intrinsic capability of residual islet cell mass to restore transiently after EMC-D induced decrease in β -cell number.

Ascorbic acid counteracts the prooxidant effect of alloxan in erythrocytes *in vitro*

Poonam Yadav*, S. Sarkar**, Nisha Rathore, Susan John, Manisha Kale and D. Bhatnagar†

Department of Biochemistry, D.A. University, Khandwa Road, Indore 452 001, India

*Department of Biochemistry, **Centre for Reproductive Biology and Molecular Endocrinology, Indian Institute of Science, Bangalore 560 012, India

Alloxan-induced experimental diabetes has been reported due to the production of toxic O_2^- and OH^\cdot radicals and H_2O_2 . Alloxan induced lipid peroxidation (LPO) in rat erythrocytes in the absence of ascorbic acid (AA). Superoxide dismutase (SOD) activity decreased while catalase (CAT) activity increased in erythrocytes with alloxan treatment without AA. Alloxan treatment in presence of AA showed no significant changes in LPO, SOD and CAT activities in erythrocytes, indicating neutralization of alloxan induced free radical production. Treatment with glucose in presence of AA showed no significant changes in LPO and in SOD and CAT activities in erythrocytes. Erythrocytes incubated with alloxan and glucose without AA showed increased LPO and decreased activity of SOD and CAT. However, LPO decreased and enzyme activities were comparable to control when treatment with alloxan and glucose was followed in presence of AA.

ALLOXAN is known to cause cytotoxicity to β -cells of

pancreas by producing highly reactive free radical species¹. The action of alloxan is inhibited by superoxide dismutase (SOD) and the enzyme has been shown to have therapeutic value in alloxan-induced diabetes². These and other studies showed the involvement of free radical species such as O_2^- and OH^\cdot radicals in the action of alloxan. In the present study, rat erythrocytes exposed to alloxan have been used as an *in vitro* model to show the action of alloxan. As the cyclic reaction involving alloxan and its reduced product dialuric acid spontaneously produce O_2^- and OH^\cdot radicals and H_2O_2 (refs 2, 3), it was intended to show whether alloxan causes changes in antioxidant enzymes in the erythrocytes. Further, whether addition of free radical scavengers such as ascorbic acid (AA) inhibits the action of alloxan. Ascorbic acid was used to investigate whether it protects erythrocytes from the prooxidant effect of alloxan. Glucose was added in physiological amounts to erythrocytes to compensate for any glucose loss during incubation and to observe the effects of alloxan in presence of glucose. In the present study, the action of alloxan *in vitro* and the protective action of AA on erythrocyte lipid peroxidation (LPO) and antioxidant enzymes such as superoxide dismutase (SOD) and catalase (CAT) were determined. The report indicates that alloxan induced LPO and changes the activities of SOD and CAT, and the action is mitigated by AA in the rat erythrocyte system.

Male Wistar rats weighing 150-180 g were housed in polypropylene cages under standard conditions with free access to drinking water and basal diet. The animals

†For correspondence.

were sacrificed by decapitation and blood was collected in 2% citrated vials by heart puncture. Blood was centrifuged and erythrocytes were washed twice in 0.1 M phosphate buffered saline (PBS, 1:9, v/v) pH 7.4 and adjusted to 5% packed cell volume (PCV). The 5% PCV was incubated in 0.1 M PBS pH 7.4 along with glucose (5 mM), alloxan (100 mM) or both with (5 mM) or without AA and incubated at 37°C for 1 h in a well-oxygenated water bath. Alloxan, glucose and AA were prepared fresh in 0.1 M PBS pH 7.4 and added immediately to the mixture. In our earlier studies, the amount of alloxan used showed significantly increased LPO in erythrocytes incubated with alloxan^{4,5}. The erythrocytes were washed thrice in PBS and were used for the assays.

LPO was estimated as malonyldialdehyde (MDA) formed by thiobarbituric acid (TBA) reaction⁶. Two ml of 5% PCV was exposed to 10 mM H₂O₂ and 2 mM sodium azide in a total volume of 4 ml 0.1 M phosphate buffer pH 7.4. The mixture was incubated at 37°C for 1 h followed by the addition of 2 ml trichloroacetic acid (28%). The cell suspension was centrifuged at 1000 g for 5 min. Four ml of the supernatant was transferred to a boiling tube to which 1 ml TBA (1%) was added and the contents were boiled for 15 min, cooled immediately and the absorbance at 532 nm was recorded in a spectrophotometer. Blank sample was prepared without H₂O₂.

SOD and CAT were analysed in erythrocyte lysate prepared by the method of McCord and Fridovich⁷. Each enzyme assay was performed in duplicate in two-fold concentration range. The SOD activity was determined by the method of Marklund and Marklund⁸ by the ability of the enzyme to inhibit the autooxidation of pyrogallol. CAT was assayed by the measurement of the decomposition of H₂O₂ (ref. 9). Haemoglobin was estimated as described by Dacie and Lewis¹⁰. Protein content in the haemolysate was determined by the method of Lowry

*et al.*¹¹. The statistical analysis was done using Student's *t*-test and the probability level of less than 5% was considered significant.

Erythrocytes were exposed to glucose (5 mM), alloxan (100 mM) or both with (5 mM) or without the presence of AA (Table 1). Glucose in physiological amounts (5 mM) showed no significant change in LPO with or without AA compared to the respective control. Alloxan increased LPO in erythrocytes compared to its control in absence of AA. However, in presence of AA, alloxan treatment showed no significant change in LPO compared to control. Alloxan and glucose without AA stimulated an increase in LPO. However, such an increase in LPO was not observed in alloxan and glucose-treated erythrocytes in presence of AA. On the contrary, the presence of AA decreased LPO in erythrocytes induced by alloxan and glucose as compared to its control.

Erythrocytes in presence of glucose without AA showed increase in SOD and CAT activities (Table 2), however, glucose in presence of AA showed no significant increase in these enzymes as compared to respective controls. Alloxan treatment without AA decreased SOD activity while the CAT activity increased in erythrocytes as compared to respective controls. In presence of AA, alloxan showed no significant change in SOD and CAT activity as compared to control. Alloxan and glucose treatment without AA inhibited SOD and CAT activity in erythrocytes. However, such an inhibition in SOD and CAT activities by alloxan and glucose treatment was overcome in presence of AA.

Alloxan induced LPO and altered the reactive oxygen scavenger enzymes such as SOD and CAT, and the effect of alloxan was mitigated with AA in rat erythrocytes. The plasma AA at increased concentrations has been reported to be an effective scavenger of free

Table 1. Effect of various treatments on LPO in erythrocytes

Treatment	LPO (nmol MDA formed/h/g Hb)	
	- AA	+ AA
Control	277 ± 08	230 ± 10
Glucose	295 ± 16 NS	249 ± 09 NS
Alloxan	354 ± 11 <i>P</i> < 0.001	206 ± 15 NS
Alloxan + glucose	400 ± 16 <i>P</i> < 0.001	185 ± 22 <i>P</i> < 0.05

LPO was expressed as nmoles of MDA formed/h/g Hb. Values are mean ± SD of 6 animals. Erythrocytes were incubated in 0.1 M PBS pH 7.4 at 37°C for 1 h with glucose (5 mM), alloxan (100 mM) or both at the concentration shown, with (5 mM) or without ascorbic acid (AA). The values in treated groups were compared with respective controls. The value of LPO in erythrocytes without incubation (0 h) was 252 ± 10 nmoles of MDA formed/h/g Hb.

Table 2. Effect of various treatments on the antioxidant enzymes in erythrocytes

Treatment	SOD (units/mg protein)		CAT (units/mg protein)	
	- AA	+ AA	- AA	+ AA
Control	269 ± 11	275 ± 15	247 ± 06	269 ± 10
Glucose	349 ± 19 <i>P</i> < 0.05	299 ± 09 NS	362 ± 13 <i>P</i> < 0.001	315 ± 12 NS
Alloxan	200 ± 10 <i>P</i> < 0.05	257 ± 15 NS	329 ± 34 <i>P</i> < 0.001	298 ± 34 NS
Alloxan + glucose	133 ± 12 <i>P</i> < 0.001	298 ± 11 NS	168 ± 17 <i>P</i> < 0.001	264 ± 14 NS

SOD and CAT activities are expressed as units/mg protein and mmoles of H₂O₂ decomposed/min/mg protein, respectively. Values are mean ± SD of 6 animals. Erythrocytes were incubated in 0.1 M PBS pH 7.4 at 37°C for 1 h with glucose, alloxan or both with or without ascorbic acid (AA) at the concentrations shown in Table 1. The values were compared with respective controls. The value of SOD and CAT in erythrocytes without incubation (0 h) was 262 ± 9 units/mg protein and 267 ± 5 mmoles of H₂O₂ decomposed/min/mg protein, respectively.

radicals in aqueous phase, more effective than any other endogenous antioxidant¹². Alloxan induced LPO in rat erythrocytes, however, such an effect was not observed in presence of AA. Glucose in physiological amounts showed no significant change in erythrocyte LPO with or without AA. However, high amounts of glucose have been shown to produce toxic oxygen species in presence of transition metals¹³.

Alloxan with or without glucose increased oxidative reaction and generation of oxygen-free radicals. These effects of alloxan were observed in absence of AA. In presence of AA no significant increase in erythrocyte LPO was observed in alloxan-treated erythrocytes with or without glucose, suggesting the role of O_2^- anion in the induction of alloxan-induced LPO in erythrocytes. AA acts as scavenger of the free oxygen species, thus lowering LPO in erythrocytes treated with AA.

The increase in SOD and CAT activity due to glucose in absence of AA may be an attempt by erythrocytes to counteract any oxidative change. However, in presence of AA, no significant change was observed in erythrocyte SOD and CAT activities or in LPO, which indicate that free radical species are effectively neutralized by AA.

Alloxan due to the production of free radical species such as O_2^- inhibited SOD activity which may be one of the reasons for increased LPO in erythrocytes. The increase in CAT activity may be due to increased production of H_2O_2 in presence of alloxan. As the changes in SOD and CAT activity in alloxan-treated erythrocytes recover towards normal in presence of AA, it is suggested that these enzymes are modified in presence of alloxan and the action is mitigated by AA. Reactive oxygen species (ROS) not only induce LPO but also modify enzymes. The involvement of ROS in the modification of protein kinase C has been suggested to be an effective on/off signal mechanism to influence cellular events¹⁴. ROS has been shown to induce signalling including activation of protein kinase¹⁴, induce protein phosphorylation¹⁵ and also act as second messenger for the expression of genes involved in the immune response¹⁶. It is probable that ROS may modify reactive oxygen scavenger enzymes and in presence of AA may show dual activation-inactivation of these enzymes.

It is concluded that alloxan due to the production of free radical species increased LPO and altered antioxidant enzymes in erythrocytes. The treatment with glucose in physiological amounts showed no effect on erythrocyte LPO but increased SOD and CAT in glucose-treated erythrocytes in absence of AA. However, no significant changes were observed in LPO, SOD and CAT activities in erythrocytes treated with glucose in presence of AA. Alloxan and glucose treatment in absence of AA increased LPO and decreased SOD and CAT activities in erythrocytes. None of these changes was observed

in presence of AA. Thus, it may be one of the processes, how the cells respond to and mitigate the ill effects of reactive oxygen intermediates engendered in biological systems by diverse processes.

Plant extracts: A non-chemical approach to control *Fusarium* diseases of mulberry

V. P. Gupta, Govindaiah and R. K. Datta

Central Sericultural Research and Training Institute, Srirampura, Mysore 570 008, India

Leaf extracts of *Azadirachta indica*, *Calotropis gigantea*, *Eucalyptus* sp., *Parthenium hysterophorous* and *Pongamia pinnata* were evaluated for their antifungal activity against *Fusarium pallidroseum* and *F. moniliforme* var. *intermedium* causing leaf blights, and *F. oxysporum* causing leaf spot diseases in mulberry (*Morus alba* L.). Leaf extract (1:5) of *P. pinnata* was highly fungitoxic to *F. pallidroseum* and *F. moniliforme* var. *intermedium* inhibiting their mycelial growth in plates by 78.2% and 84.3%, respectively; whereas *C. gigantea* and *A. indica* were most effective

against *F. oxysporum* inhibiting its mycelial growth by 78.5% and 73.2%, respectively. Under greenhouse conditions, aqueous leaf extract (25%) of *P. pinnata* reduced the incidence of leaf blights caused by *Fusarium pallidorozeum* and *F. moniliforme* var. *intermedium* by 63.6% and 67.1%, respectively; whereas in case of leaf spot caused by *F. oxysporum*, *C. gigantea* and *A. indica* both were effective in reducing the leaf spot incidence by 60.2% and 57.2%, respectively.

In mulberry, *Fusarium* diseases are the most destructive ones which are prevalent in all the southern states of the country where sericulture is generally practised. These diseases are observed in all the seasons with varying degree of disease incidence (3.0–19.5%) which reduce the leaf yield and its nutritive value, and make mulberry leaves unsuitable for silkworm feeding¹⁻³. Therefore, keeping in view the seriousness of *Fusarium* diseases in mulberry, and possible harmful effects of chemical fungicides on silkworm growth and development, there is a need to develop a non-chemical, eco-friendly method for the control of these diseases.

In the recent past, the angiospermic plants are proved to be a useful source of fungitoxic substances that are rather harmless compared to synthetic chemical fungicides which often impose undesirable side effects. Several plants have been reported to possess substances which are toxic to microbial pathogens and serve as protective barriers to infection⁴. The present investigation was, therefore, undertaken to test the efficacy of leaf extracts of *Azadirachta indica* A. Juss., *Calotropis gigantea* (L.) R. Br., *Eucalyptus* sp., *Parthenium hysterophorus* L. and *Pongamia pinnata* (L.) Pierre against *Fusarium* species, viz. *F. pallidorozeum* (Cooke) Sacc., *F. moniliforme* Sheldon var. *intermedium* Neish & Leggett and *F. oxysporum* Schlecht. causing leaf blights and leaf spot diseases in mulberry^{2,3}.

Twenty-five grams of fresh leaves of each plant species, viz. *Azadirachta indica*, *Calotropis gigantea*, *Eucalyptus* sp., *Parthenium hysterophorus* and *Pongamia pinnata* (washed well 2–3 times with tap water and once with distilled water) were ground in 100 ml of sterile distilled water. The macerate was squeezed through double-layered muslin cloth and centrifuged at 5,000 rpm for 20 min. The supernatant was filtered through Whatman No. 1 filter paper and then sterilized by passing through the Seitz filter (G5). The extract (25%) thus obtained was used for the *in vitro* experiments. For *in vivo* greenhouse experiments, the macerate obtained after squeezing through double-layered muslin cloth (25% aqueous leaf extract) was directly used for spraying plants.

For evaluation of antifungal effect of leaf extracts on mycelial growth of *Fusarium* species in plates, potato dextrose agar medium was amended with filter-sterilized fresh leaf extract (25%) to get dilution of 1:5, 1:10,

1:20 and 1:30 (extract:medium). The medium devoid of leaf extract served as control. The medium was poured into Petri plates (90×17 mm) at 15 ml/plate. The plates were inoculated centrally with a 4 mm mycelial disk (cut from the edge of 5-day-old actively growing colonies) of each species of *Fusarium*. Four replicates were maintained for each dilution and control. The whole set of experiment was incubated at 28±2°C and mean radial growth of fungal colony was recorded after a week. The fungitoxic efficacy of leaf extract was determined by comparing the radial growth in treatment (T) with the control (C). The inhibition percentage (I) was calculated by following the formula⁵: [I = (C – T/C) × 100].

Leaf extracts found effectively inhibiting the growth of *Fusarium* species on plates, were tested *in vivo* under greenhouse conditions. Extracts of *P. pinnata*, *C. gigantea* and *A. indica* were tested against leaf blights caused by *F. pallidorozeum* and *F. moniliforme* var. *intermedium*, whereas *C. gigantea* and *A. indica* were tested against leaf spot caused by *F. oxysporum*.

Mulberry (*Morus alba* L.) var. Kanva 2 plants, susceptible to *Fusarium* species tested, were raised from healthy cuttings and grown in earthen pots (40 cm) in a greenhouse at 28±2°C with relative humidity of 75%. Three sets of required number of potted plants (2-month-old) were inoculated separately with *F. pallidorozeum*, *F. moniliforme* var. *intermedium* and *F. oxysporum* by atomizing their freshly prepared uncontaminated spore suspensions (1×10⁶ conidia/ml) on to the leaves of plants. Inoculated plants were covered individually with a moist polythene bag for 24 h. After 72 h of inoculation, aqueous leaf extracts (25%) of *P. pinnata*, *C. gigantea* and *A. indica* were sprayed separately on to the leaves of plants inoculated with *F. pallidorozeum* and *F. moniliforme* var. *intermedium*; whereas extract of *C. gigantea* and *A. indica* were sprayed on to the leaves of plants inoculated with *F. oxysporum*. The extracts were sprayed twice at an interval of one week. Three replications of 5 plants each (total 15 plants) were maintained for each extract and *Fusarium* species, and the same number of plants from each *Fusarium*-inoculated set were sprayed with sterile distilled water which served as control. All the replications, including control, were arranged in a randomized block design. Disease intensity was recorded in treated and control plants after 30 days of second spray. From the observations, the per cent disease incidence (PDI) values (severity of disease) were calculated according to the FAO formula for plant disease assessment in different grades⁶.

$$PDI = \frac{\text{Sum of numerical values}}{\text{Total number of leaves observed} \times \text{Maximum grading (5)}} \times 100.$$

The sum of numerical values was obtained by mul-

RESEARCH COMMUNICATIONS

tipling the number of leaves observed in a particular grade with their respective grading as given below: 1=No infection; 2=up to 5% of leaf area affected; 3=6–25% of leaf area affected; 4=26–50% leaf area affected; and 5=51–100% leaf area affected.

From the PDI in control (PC) and treatment (PT), the per cent disease control (PDC) was calculated by following the formula: $[PDC = \{(PC - PT)/PC\} \times 100]$.

The per cent inhibition data (Table 1) were statistically analysed by subjecting them to ANOVA, whereas qualitative PDI data were analysed by following Mann-Whitney *U* test.

In order to confirm the results, each experiment was repeated three times.

Significant reduction ($p \geq 0.05$) in radial growth of *F. pallidoroseum*, *F. moniliforme* var. *intermedium* and *F. oxysporum* was observed with leaf extracts of *A. indica*, *C. gigantea*, *Eucalyptus* sp. and *P. pinnata*. However, extracts of *P. hysterophorus* stimulated the growth of all *Fusarium* species, even at a lower concentration of 1:30. The inhibition effect of leaf extracts was directly correlated with their concentration which increased with the concentration of extracts. Both the leaf blight causing *F. pallidoroseum* and *F. moniliforme* var. *intermedium*

showed similar trends of inhibition in their mycelial growth, however, *F. oxysporum* causing leaf spot disease differed from these two species in responding to leaf extracts.

Leaf extracts of *P. pinnata* was highly fungitoxic at all concentrations to *F. pallidoroseum* and *F. moniliforme* var. *intermedium* inhibiting their radial growth in plates by 63.1–84.3%; whereas *Eucalyptus* sp. was least effective to both *Fusarium* species, even at a high concentration of 1:5 as it showed only 30.5% and 22.0% growth inhibition, respectively. *C. gigantea* was moderately effective against both the leaf blights causing *Fusarium* species inhibiting 50.3–71.8% growth (Table 1 and Figure 1).

Leaf extracts of *C. gigantea* and *A. indica* were found to be most effective at all concentrations against *F. oxysporum* inhibiting 58.5–78.5% and 59.7–73.2% growth, respectively. *P. pinnata* extract, though highly fungitoxic to both the leaf blight causing *F. pallidoroseum* and *F. moniliforme* var. *intermedium*, exhibited least inhibition potential (0.8–12.2%) against leaf spot causing *F. oxysporum* (Table 1 and Figure 1).

Leaf extracts of *A. indica* and *P. pinnata* have earlier been reported inhibiting the mycelial growth of various

Table 1. Fungitoxic potential of leaf extracts against *Fusarium* species *in vitro*

Plant species	Conc. of extract	Inhibition/stimulation (+) percentage

Figure 1. Fungitoxic potential of leaf extracts against *Fusarium* species *in vitro*.

Figure 2. Efficacy of leaf extracts in controlling the *Fusarium* diseases of mulberry.

Fusarium species^{7,8}, which is in agreement with the present findings. Leaf extracts of *Eucalyptus* sp. and *C. gigantea* have also been known for their antifungal activity against various fungal pathogens^{9,10}. However, these extracts have not been studied against any species of *Fusarium*. The inhibitory effect of all these leaf extracts on mycelial growth might be attributed to the presence of antifungal ingredients in them^{8,9,11}. *P. hysterophorus* leaf extract, though reported for its antifungal properties against *F. oxysporum* and some other fungal pathogens^{12,13}, is found stimulatory to *Fusarium* species infecting mulberry. It may be due to the variations in response of different *Fusarium* species and formae speciales to the leaf extracts⁴.

In greenhouse experiment, leaf extracts of *P. pinnata*, *C. gigantea* and *A. indica* were proved to be fungicidal

as these extracts significantly controlled the leaf blights and leaf spot diseases caused by *Fusarium* species in mulberry. Aqueous extract (25%) obtained from the fresh leaves of *P. pinnata* showed better fungicidal potential by reducing the disease severity (PDI) of *F. pallidoroseum* and *F. moniliforme* var. *intermedium* leaf blights by 63.6% and 67.1%, respectively. In the case of leaf spot caused by *F. oxysporum*, leaf extracts of *C. gigantea* and *A. indica* were able to control the disease severity by 60.2% and 57.2%, respectively (Figure 2). These results are in agreement with the earlier observations¹⁰, particularly in case of *C. gigantea* and *A. indica* which have been reported to reduce the disease severity of leaf spot caused by *Cercospora moricola* in mulberry. However, contrary to the earlier report¹⁰, in the present study the leaf extract of *P. pinnata* is highly effective in controlling the leaf blights caused by *F. pallidoroseum* and *F. moniliforme* var. *intermedium* in mulberry. This is the first report on evaluation of leaf extracts for the control of *Fusarium* diseases of mulberry under realistic conditions in greenhouse.

All the leaf extracts tested were found to be fungicidal, but non-phytotoxic in nature. Thus, these extracts can be exploited for the control of *Fusarium* diseases of mulberry.

Geochemical analysis of iron oxide/hydroxide coated and uncoated non-magnetic component of the bulk sample: Possible utility of the coated component in a stream sediment survey for gold

K. Bheemalingeswara

Department of Geology, University of Delhi, Delhi 110 007, India

The possible relationship between the secondary Fe-oxides/hydroxides and particulate gold in the surfacial environment is presented in this communication. Coated non-magnetic component separated from bulk, using isodynamic separator, shows much higher values for gold compared to the same of the uncoated. The increase in concentration is related to the possible affinity between the secondary oxides/hydroxides and particulate gold and the abundance of the two in the area. Possible affinity between these oxides/hydroxides and colloidal, fine/dust particles, etc. of gold may make the total coated component (coated magnetic + non-magnetic) useful to provide an additional data on adsorbed gold apart from particulate. Positive relationship between iron oxides/hydroxides and gold values suggests the utility of the total coated component in general and coated non-magnetic component in particular in stream sediment survey for gold.

THERE are many reports in the literature about the presence of Fe-oxide/hydroxide coating in secondary environment, particularly in the zone of weathering and its relation to gold¹⁻⁵. It is also observed that the lateritic gold enrichment can be associated with the formation of colloidal gold and its interaction with the iron-oxide-rich medium. Adsorption of colloidal gold on synthetic goethite and hematite was measured experimentally at 25°C and it was observed that the affinity rate depends more on the composition of the medium. Inert electrolytes, if present, are expected to enhance the effect⁶. This information provides the impetus to study the relationship between the iron oxide/hydroxide coating and the particulate gold.

The shortcomings in the sample-processing scheme to separate iron oxide/hydroxide-coated particulate gold from heavy mineral concentrate⁷ and its implications on gold exploration are discussed earlier by the author⁸. The utility of another component, i.e. the total iron oxide/hydroxide-coated component in general and coated non-magnetic component in particular of the bulk sample in gold exploration is reported here.

Stream sediment samples collected earlier during an orientation survey for gold from an area known for Au and Cu mineralization near Bhiwapur, Nagpur district, Maharashtra⁷ were used in this study. Details about

geology of the area, sampling, etc. are provided elsewhere⁷. About 1 kg of partly iron oxide/hydroxide-coated -30+50 mesh size (-0.59+0.297 mm) bulk sample was run in a isodynamic separator at 1.2 Å (25° forward/15° side slope) to separate magnetic and non-magnetic components⁷. Magnetic component in this case contains iron oxide/hydroxide-coated magnetic and non-magnetic minerals plus uncoated magnetic minerals. So, both coated magnetic and non-magnetic minerals form the total coated component present in the sample. Since we mainly deal here with the coated non-magnetic component, the total coated component was treated with dilute HCl (to remove coating) before further separating the earlier coated non-magnetic minerals⁷. The non-magnetic component thus separated at two stages firstly, from bulk and secondly from the total coated component, was analysed separately for gold.

Fifty grams of the first and 20 g of the second stage non-magnetic component were separately ground approximately close to -120 mesh size. It was then transferred into a beaker and treated with 50-60 ml acid mixture (hydrobromic acid + few drops of bromine solution)^{7,9}. The sample was then washed and transferred into a 100 ml volumetric flask containing 10 ml iso-butyl methyl ketone (MIBK). After shaking the solution for few minutes, the organic layer was analysed for gold using AAS (Perkin-Elmer, 2380) at Department of Geology, University of Delhi. The data thus generated are presented in Table 1.

The secondary oxides/hydroxides of Fe, Mn, etc. known to be active in the surfacial environment, not only coat the grains⁷ of different sizes but also facilitate accumulation of ionic, colloidal⁶ dust or fine particles^{1,2}, etc. of different minerals or elements through absorption and adsorption processes. In the present case, about 4-22%

Table 1. Gold data (in ppm) on iron oxide/hydroxide coated and uncoated non-magnetic component and approximate percentage of coated non-magnetic and total coated component in the bulk sample

Sample number	A	B	C	D
1	0.1	0.6	10	20
2	0.1	0.4	11	22
3	0.1	0.5	7	14
4	< 0.1	0.2	6	12
5	0.1	0.3	7	14
6	0.1	0.2	6	12
7	< 0.1	0.3	7	14
8	< 0.1	0.2	4	8
9	< 0.1	0.1	6	12
10	< 0.1	0.1	3	6
11	< 0.1	< 0.1	3	6
12	0.1	< 0.1	2	4
13	< 0.1	0.1	3	6

A, Uncoated non-magnetic of the bulk sample.

B, Coated non-magnetic of the bulk sample.

C, Approximate percentage of coated non-magnetic component.

D, Approximate percentage of total coated component (i.e. coated magnetic + non-magnetic).

(assuming to be twice the amount of coated non-magnetic grains/minerals (Table 1)) of the grains ($-30+50$ mesh size) are estimated to be coated by these oxides. Thus it is important to understand the pattern of coating either selective or random. Since these oxides are also known to coat the gold grains⁷, it is also important to understand the relationship between them in terms of geochemical survey.

Data (Table 1) generated on coated non-magnetic component ($<0.01-0.6$ ppm) compared to that of the uncoated ($<0.01-0.10$ ppm) component show much higher values for gold. These enhanced values not only suggest the possible affinity between these oxides/hydroxides and gold but also the relationship of particulate gold with the intensity of these coatings. Since about 2–11% of the bulk sample comprises iron oxide/hydroxide-coated non-magnetic grains, the values recorded for gold in the non-magnetic component either low (of first stage) or high (of second stage) are expected to be influenced by these percentages. It is well reflected in the gold values of the coated non-magnetic component where sample no. 1, coating being approximately 10%, shows 0.6 ppm and sample no. 9, with 6% shows only 0.1 ppm. This relationship, though not exactly linear is also seen in Figure 1.

The data not only confirm the earlier report on gold nuggets recovered from such similar component⁷ but also indicate the possible utility of such coated non-magnetic component in a stream sediment survey for gold.

The above observation together with the experimental data on colloidal gold⁶ probably indicate the possible affinity of these oxides not only to particulate but also to colloidal, dust/fine particles, etc. of gold in the secondary environment. Though the proportion of gold (different forms) that is going to be enriched in the presence of these oxides is not clear, their role in influencing particulate gold values (Table 1) and colloidal gold⁶ is better understood. Thus, coatings become useful to provide information on both particulate and adsorbed gold. In the case of particulate gold, only the coated non-magnetic component, i.e. 2–11% (present case) is utilized. Whereas in the case of adsorbed gold the total coated component about 4–22% (i.e. coated magnetic + non-magnetic) is utilized.

Hence, the presence of iron oxide coating on the one hand affects the separation of particulate gold in the case of HMC⁷ and on the other may provide useful information on colloidal, dust/fine particles, etc. of gold, apart from particulate (Table 1) in the case of total coated component of the bulk sample.

Further, it is suggested that there is a need for a suitable sample-processing scheme, where the secondary iron oxides/hydroxides are conspicuous, to recover both

Figure 1. Positive relationship between the percentage of coated non-magnetic component vs gold concentration.

absorbed and adsorbed gold apart from particulate from bulk sample.

To conclude, iron oxide/hydroxide-coated non-magnetic component yields higher values for gold (particulate) compared to the uncoated component. Possible affinity among Fe-oxide/hydroxide and colloidal⁶, dust/fine particles, etc. of gold makes the total coated component important for adsorbed apart from particulate gold. Since a positive relationship is observed between the intensity of coating and gold values (of particulate), a similar trend may be expected also in the case of adsorbed gold. Coated component like heavy mineral concentrate seem to have some application in geochemical survey for gold, particularly in areas where iron oxide coating is quite conspicuous.

Chitinozoa and melanosclerite from the Lower Paleozoic sequence of the Tethyan Garhwal Himalaya – A note on their identification and distinction

H. N. Sinha, S. S. Srivastava, P. N. Kapoor* and Rajesh Chauhan*

Department of Earth Sciences, University of Roorkee, Roorkee 247 667, India

*K.D.M. Institute of Petroleum Exploration, ONGC Ltd., Dehradun 248 195, India

Sediments of the Shiala and Yong Limestone formations belonging to the marine Lower Paleozoic sequence in the Tethyan Garhwal Himalaya have yielded a rich assemblage of acritarchs. In addition to prolific occurrence of acritarchs, these sediments have also yielded rare to infrequent chitinozoa and melanosclerite. It is pointed out that the distinction between these two distinct palynological entities is rather difficult through the conventional microscopic examination. The present paper highlights the subtle and minor differences in the morphologies of the two which could be seen only through SEM. Thus, a thorough rechecking and revision of earlier records is necessary for correct identification.

The present study reveals the occurrence of rare presence of chitinozoa and melanosclerite along with prolific acritarchs¹ from the Shiala and Yong Limestone formations. These formations of the Tethyan Garhwal Himalaya are well exposed in and around the village Sumna (30°40'N, 80°50'E) of the Chamoli district of the Garhwal Division, Uttar Pradesh. The lithostratigraphic framework at Sumna has already been described^{2,3} (Table 1).

The Garbyang Formation grades into the Shiala Formation without any lithological change². Four biostratigraphic zones have been established based on macrofauna and Middle to Upper Ordovician age has been assigned to the Shiala Formation^{2,3}. However, Middle Ordovician age is assigned to the Shiala Formation based on conodont species⁴. But, Caradocian to Wenlockian age is assigned to the Shiala Formation based on the acritarch assemblages recorded¹. The Yong Limestone is biohermal in nature and is recognized as a separate lithostratigraphic unit, named as the Yong Limestone Formation which conformably overlies the Shiala Formation. An Upper Ordovician to Lower Silurian age has been assigned to the Yong Limestone^{2,3,5}. However, Sinha *et al.*¹ have dated the Yong Limestone Formation to be of Late Silurian age (Ludlovian) based on acritarch assemblage.

The method of preparation of strato-litho-petrographic column and the traverse direction for sample collection along the Sumna-Rimkhim section has been described elsewhere¹.

The samples collected from the Shiala and the Yong Limestone formations are clastics and non-clastics which include mainly fine-grained calcareous quartz arenite, siltyshale and wackstone (bioclast).

From each sample, 50 g of pea-sized rock material was dissolved first in hydrochloric acid and then in hydrofluoric acid and finally in nitric acid. The macerated and decomposed material was washed four times with distilled water by centrifuging. Material thus obtained was treated with heavy liquid using KI, CdI₂ and ZnI. The permanent slide was prepared by adding 2 drops of polyvinyl alcohol into the residue. All the slides and samples are deposited at the Department of Earth Sciences, University of Roorkee for future reference.

Chitinozoans are a group of acid-resistant microfossils whose biological affinities are yet to be ascertained⁶⁻⁸. It is believed that they represent the eggs or egg capsules of a soft-bodied metazoan^{9,10}. They occur singly or in colonies⁷, containing twelve or more individual vesicles⁶. Few chitinozoans show polymorphism phenomenon⁷. Eisenack¹¹ first recorded chitinozoans in Germany in 1931. Chitinozoans have been described from almost all the continents, with the single exception of Antarctica¹². They are exclusively marine planktic microfossils found in sedimentary rocks ranging in age from Ordovician to Devonian⁸. They have been reported from Mississippian rocks also¹³. They occur in Paleozoic shale and limestones; and are found to be rare in coarse grained limestone and sandstone due to the winnowing action of prevailing current¹⁴. They are generally flask-shaped¹⁴ and range in size from 60 to 2,000 microns¹⁵ but the majority of species have a size range between 100 and 300 microns⁶. Due to their rapid evolution, wide distribution and short ranging species of chitinozoa permit a detailed biozonation of Palaeozoic strata^{8,15}. It has been shown that the detailed chitinozoan biozonation is possible in sediments that have undergone greenschist facies metamorphism¹⁶. The first global chitinozoa biozonation for the Silurian has been proposed based on short ranging, well-defined and easily identifiable index

Table 1. Lithostratigraphic framework of the Tethyan Garhwal Himalaya (Sinha, 1989)

Time unit	Lithounit	Generalized lithology
Silurian	Yong Limestone Formation	Green nodular limestone
Ordovician	Shiala Formation	Sandstone, quartzite, limestone, alternate bands of sandstone and shale, alternate bands of greenish shale and limestone
	Garbyang Formation	Green needle shale with occasional bands of limestone, sandstone and shale

Features	Chitinozoans	Figure no.	Melanosclerites	Figure no.
Thickness of wall	Thin walled*	2 c	Thick walled*	2 d, e, i, j
Nature of vesicles	Hollow vesicles	2 c, f, g	Generally not hollow	2 a and b
Nature of central canal	—	—	Very small central canal	2 h

Light microscopic studies shown in Figure 1 a, b, d, e, g, i-t (Palynological slide) could either be chitinozoans or melanosclerites.

*Thickness of wall of melanosclerites is relatively more than the thickness of wall of chitinozoans in general.

species⁸. The chitinozoans are found to be most diverse and abundant in the subtidal deposits¹⁷.

The palaeogeographical studies of chitinozoan distribution are scanty¹⁸. However, the chitinozoan provincialism is less pronounced in Silurian than in the Ordovician on generic level^{18,19}.

The chitinozoa described from the Shiala and the Yong Limestone formations are black and very glossy under normal light (Figure 1). The black colour of fossils may be due to progressive increase of the carbon ratio, i.e. overmaturity²⁰ caused by eometamorphism²¹. Cramer *et al.*²¹ suggested that the black colour of chitinozoa is possibly due to the temperature exposure of about 200°C.

The term 'Melanosclerite' was first used by Eisenack²² to identify the problematic microfossils ranging in age from Ordovician to Middle Devonian (Eifelian age)²². Melanosclerites are exclusively marine rod-shaped microfossils with pseudochitinous wall composition²³, i.e. not very close to true chitin but similar to the composition of the shells of the Recent *Thecamoeba Gromia oviformis*²⁴. They have not been widely studied and are considered to have some affinity with hydrozoans²³. An algal origin for melanosclerites is also suggested²⁵. They are strongly facies controlled and restricted in sediments formed under open ocean conditions²⁶. However, Cashman²³ found a similarity in ecology and latitudinal occurrence between the modern cubomedusa, *Carybdea alata* and melanosclerite *Melanostylus coronifer*. This could be helpful in palaeoenvironmental and palaeogeographical reconstructions. More study on this problematic microfossil is required for better understanding on the phylogenetic history and their distribution through Phanerozoic. This would help in biostratigraphy and palaeoenvironmental interpretation²³.

The melanosclerites and chitinozoans recovered from the Shiala and the Yong Limestone formations of the Tethyan Garhwal Himalaya are poorly preserved. The chitinozoans recovered by the earlier workers are from the Vindhyan Supergroup (Sone Valley)²⁷; Pin dolomite, Spiti²⁸; Yong Limestone, Garhwal⁵, Spiti²⁹ and Satpuli, Garhwal³⁰. However, the published literature has no record of chitinozoans from the Shiala Formation. In the present study, the generic identification of some of

the recovered chitinozoans from Shiala and Yong Limestone formations has been done, which are long ranging in age. They are *Ancyrochitina* sp., *Desmochitina* sp., *Conochitina* sp. (Figures 1 and 2). The generic and specific identification of melanosclerites was not attempted during the present study.

Owing to a very close similarity in size and nature of silhouette of chitinozoans and melanosclerites, there exists every possibility of erroneous identification. It was found that many previously described and illustrated chitinozoan taxa proved to be unworkable when light microscope studies were replaced by routine SEM investigation¹². Thus, a form identified through a microscope as a chitinozoan may in fact be a melanosclerite. Hence, it may be pointed out that the earlier reports, records and illustrations published particularly from Indian subcontinent may require reexamination, checking, correction and revision through SEM.

In view of this information, the present material was carefully handled and examined before sending for publication.

The principal distinguishing features (which can be seen only under SEM) between the two distinct palynological entities are tabulated in Table 2.

Gas-charged sediments in shallow waters off Redi along the central west coast of India

L. V. Subba Raju and B. G. Wagle

National Institute of Oceanography, Dona Paula, Goa 403 004, India

This study reports the occurrence of gas-charged sediments in the nearshore areas of the west coast of India. High resolution shallow seismic reflection profiles on the nearshore area along central west coast of India, at water depths of 11-18 m are characterized by anomalous seismic subbottom signatures in the form of acoustic turbidity which extends from the underlying reflector and reach within 4-5 m of the seafloor. Fine grained sediments apparently contain appreciable quantities of interstitial gas bubbles which are responsible for the anomalous seismic sig-

natures. This could be due to shallow hydrocarbon gases, mostly methane, which might have been derived due to the biogenic degradation of organic matter accumulated under palaeo-estuarine conditions. These gas-charged sediments pose a potential hazard for the offshore engineering constructions. Hence, the detection of these sediments forms an essential part of any offshore site investigation programmes.

The western continental shelf is widest off Cambay (345 km) and it narrows down (60 km) off Quilon. It is characterized by gently dipping seafloor, with an average gradient of 1:400-1:3000, and the shelf break occurs at 80 to 140 m water depths. The inner shelf up to 50-60 m water depths is marked by even topography and is carpeted by silts and clays while middle and the outer shelf show uneven to rough topography with a thin layer of calcareous sands.

Recent developments in marine geophysical techniques have made it easier to identify gases in shallow marine sediments. Based on shallow seismic, side scan sonar and echogram results, gas-charged sediments have been reported from most of the world's continental shelves¹⁻⁵. The addition of gaseous phase compounds to the otherwise fluid saturated seafloor sediments significantly alters the acoustic properties of the seafloor^{6,7}. These effects produce readily identifiable anomalies in high resolution subbottom reflection profiles of the shallow seafloor⁸⁻¹⁰. Though the occurrence of shallow gas-charged sediments is documented on the western continental margin of India using seismic signatures¹¹⁻¹⁴, little or no similar information is available so far regarding these in nearshore areas. Here we report the occurrence of gas-charged sediments in the nearshore areas of the west coast of India.

The study area lies in the shallow waters off Redi,

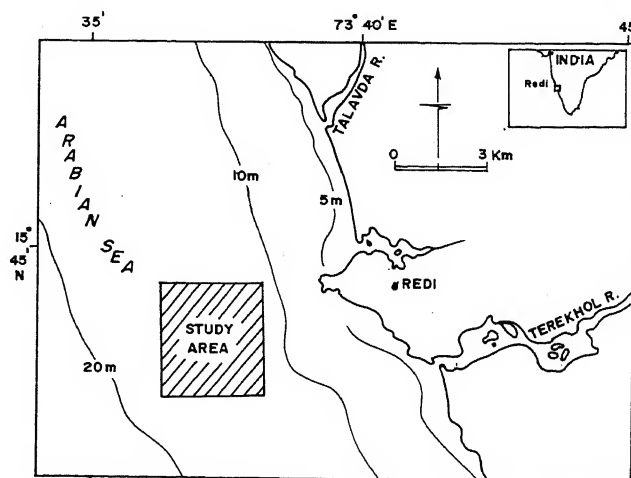

Figure 1. Map showing the survey area off Redi. Inset shows the location of Redi along the west coast of India.

about 400 km south of Cambay (Figure 1). Our data base comprises echosounding (Atlas Deso-10, 210 and 30 kHz), side scan sonar (EG&G, Mark IB, dual channel recorder 259-3 and tow fish 272) and high resolution shallow seismic profiling (300 joules and 400-5000 Hz). The survey tracks are approximately spaced 25 m apart in north-south and east-west grid fashion (Figure 2). The positions of the tracks were fixed by Mini Ranger MRS III system and a total of 500 line kms were covered.

In the study area, water depth ranges from 11 to 18 m and is dominated by gently westward sloping seafloor and it lies off the mouths of the rivers Talavda and Terekhol. The area is essentially featureless with the seafloor formed by silty clays. Shallow seismic records indicate that acoustically transparent clays with an assumed velocity of 1.5 km/sec range in thickness from 10 to 15 m cover the seabed. These clays are underlain by sandy reflectors. These acoustically transparent clays are marked by a sudden appearance of extensive patches of shallow gas-charged sediments in the form of 'acoustic turbidity', at places resembling inverted U-like features, where the reflections are chaotic caused by the scattering of the acoustic energy (Figure 3 a, b, c). The velocity in the gas-charged sediments is generally decreased depending upon the degree to which gas bubbles in

sediments act as a resonant system and the relation of acoustic frequency to the bubble-sediment resonance frequency¹⁵.

Acoustic turbidity is the term generally used to refer to those parts of the seismic studies where subbottom details are lost due to the effects of gas bubbles within the sediment pore spaces⁴. These acoustic turbid masses reach within 4-5 m of the seafloor. The sides of the turbid zones are nearly vertical. Their top edges are either flat or rounded. The records are similar to some of the published records of gas-charged sediments reported earlier^{1,11,13,14} in the outer shelf. The area covered by the present study is roughly 12 km² and it is estimated that 10-15% of the area is characterized by gas-charged sediments.

The anomalous features are confined only to the shallow seismic records and are not seen either in the corresponding echograms or in the sonographs. This reveals that the anomalous features due to gas are localized within the sediments but not surfacing out of the seabed, though upward migration of gases by either molecular diffusion or bubble formation from the sediments into the overlying waters could be possible¹⁶.

Figure 2. Survey tracks along which bathymetric, side scan sonar and shallow subbottom seismic profiling were carried out.

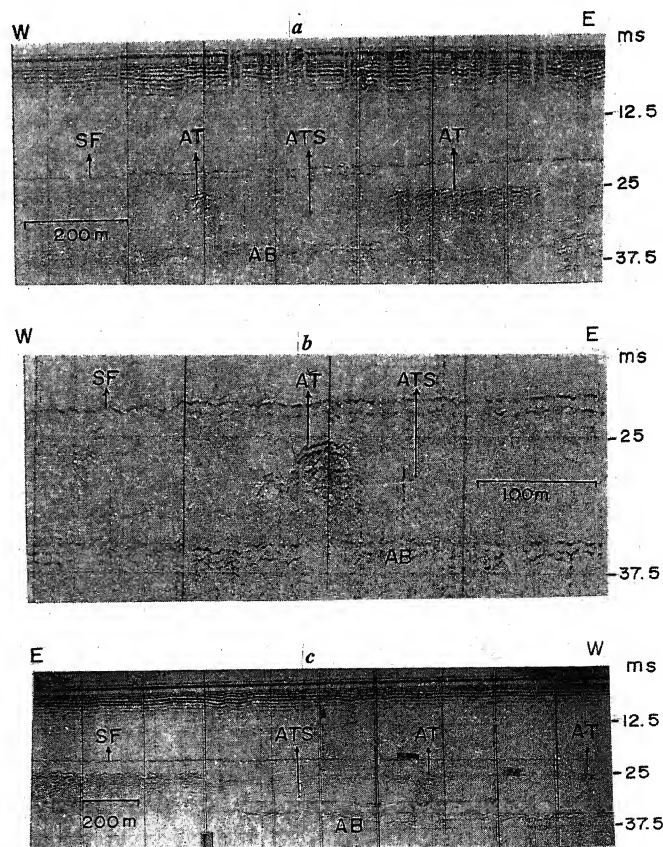

Figure 3 a-c. Seismic records showing examples of acoustic turbidity on high resolution seismic reflection profiles (300 J and 400-5000 Hz).

Shallow hydrocarbon gas, mostly methane has been reported from the western continental margin of India^{11-14,17} and from Amazon submarine deltaic regions¹⁸ elsewhere. According to Kaplan¹⁹, gases in the marine sediments could be from four different sources, viz. atmospheric, biogenic degradation of organic matter, upward diffusion by thermocatalytic cracking of more complex compounds and submarine volcanic or geothermal processes. Siddiquie *et al.*¹¹ indicated two probable possibilities for the gas on the western shelf, i.e. biodegradation of organic matter or thermocatalytic cracking of more complex compounds. Similarly Karisiddaiah *et al.*¹³ believed that these gases could be from biogenic sources or geothermal processes or both. Karisiddaiah and Veerayya¹⁴ emphasized the role of vegetation as the source for the accumulation of methane gas. Paropkari *et al.*²⁰ reported high organic carbon content in the western shelf of India. Mascarenhas *et al.*²¹ reported peat deposits intercalated in sediments from the inner shelf.

It is known that bacterial methane formation is common in more rapidly accumulating marine sediments with higher organic matter contents once the dissolved sulphate has been utilized²². Obviously, the primary requirement for the existence of such gases is the availability of sufficient organic matter below the seafloor and appropriate time for generation of sufficient gas molecules and enough permeability of the sediments required for gas to collect as bubbles²³.

The proximity of the study area to the mouths of the Talavda and Terekhol rivers, gives the high possibility that the offshore sediments may be sufficiently organic-rich to generate sufficient quantities of biogenic gas and to produce the observed seismic signatures. High rate of sedimentation at the river mouths which results in rapid burial of organic matter must have also triggered the gas formation. Since the occurrence of methane gas in the outer shelf sediments is reported earlier¹¹⁻¹⁴, this gas is also believed to be methane and of bacterial origin. As mentioned earlier, similar occurrences of shallow gas formations from deltaic sediments and from nearshore sediment containing organic-rich layer have been reported from the world's continental shelves²⁴⁻²⁸.

Methane is a powerful greenhouse gas^{29,30} which plays an important role in atmospheric chemistry by influencing both the ozone concentration and the infrared radioactive flux³¹. Similarly, the various effects of gas on the geotechnical behaviour of fine grained soils create the potential hazard for offshore construction and development. When the gas gets trapped and accumulates under an impermeable layer, the resulting gas pressure goes up to such a level that a blowout can occur during drilling. Similarly, gas escaping naturally to the surface in extreme cases causes the collapse of structures due to undermining of the foundation⁴. Hence, the gas

detection studies now form an essential part of any marine site investigation programmes.

Undoubtedly, there could be similar shallow sedimentary methane reservoirs in the Indian shelves associated with major buried palaeo-deltas of the rivers, buried fluvial systems, infilled palaeo-river channels, nearshore bays, estuaries, etc. More detailed and systematic studies of these areas, incorporating high resolution seismic subbottom profiling, will certainly unravel the reservoirs of natural gas accumulation.

The inventor of the jet engine

An obituary of Sir Frank Whittle

There was a certain poignancy to the news that Sir Frank Whittle, who could, if any one could, be called the inventor of the jet engine, had passed away on 10 August 1996, at the age of 89. This was because so few were even aware that this remarkable man was still now, alive; this age has no patience with modesty. I came to hear of his death from a small obituary in the *Deccan Herald*. And there was an unintended irony even here: the obituary of this living legend was directly below a column listing the winners of one of our numerous scientific awards. Whittle, an introvert of sorts, had a hard time getting any recognition at all, while now, especially in our country, recognition usually goes to those adept at self-advertisement who shout the loudest or who have someone to shout for them. It is not easy to be heard in the noisy market place; such are our times.

Frank Whittle was born in Coventry, Warwickshire, on June 1, 1907, to parents of apparently modest means. At the age of 16 he entered the Royal Air Force as an apprentice, studied at the Royal Air Force College, the Central Flying School and the RAF School of Aeronautical Engineering, Cranwell, before being posted to a fighter squadron in 1928. Besides teaching flying, Whittle served as a test pilot at the Marine Aircraft Experimental Establishment, Felixstowe, during the years 1931–32. This was followed by further studies at the RAF engineering school and at the University of Cambridge. While his basic ideas on

the jet engine date back to 1928, when he was a young cadet in the RAF, his confidence in the correctness of these ideas must have grown with his increased technical knowledge acquired during his post-graduate studies. Thus he was well prepared to put his ideas into practice when shortly before the war, in 1937, he was attached to Power Jets Ltd., to develop gas turbines for the jet propulsion of aircraft.

Without an historical perspective it would be impossible, especially at a time when jet travel is common place, to properly assess the immensity of Whittle's achievement. He was among the first, if not the first, to conceive of a well-defined engine based on jet propulsion. He was the first to show, using general thermodynamic arguments, that the engine was technically feasible. With a small staff of a couple of draughtsmen and a few other assorted assistants he then designed the component parts of the engine, i.e. the compressor, the combustor, the turbine, etc; he then had these built and then did the testing himself at considerable personal risk to himself and his small staff. Against almost impossible odds he had the prototype engine built to be test flown on a specially built Gloster E28/39 airframe. That first test flight on May 15, 1941, was successful. So the man conceived the idea, worked out the details, supervised the manufacture and had the prototype test flown, with the assistance (after 1937) of a staff of less than 10 people and a total cost (after 1937) of

a few thousand pounds! A human and engineering saga that would thrill even the most jaded.

The rest of the story, however, is depressing. Once the idea was proved successful, the forces that be decided that the invention was too important to have its further development be entrusted to as small a man as Frank Whittle. He was made an adviser to the Ministry of Supply in 1946, retired from the RAF with rank of Air Commodore in 1948, and in the same year knighted and bought off with a government award of 100,000 pounds, tax free! But no more involvement with the love of his life. Considering the current size of the jet engine business, the sum awarded appears ridiculously small in these days of intellectual property rights and the Bill Gateses. A story repeated many times since the days of Archimedes of Syracuse. It appears that his intense disappointment, at having failed to gain control over his invention, led to a nervous breakdown. He emigrated to the United States soon after, retiring in 1979 as an adjunct professor at the US Naval Academy.

I first came to know of Whittle's inspiring story from a superb biography that I accidentally found at the Indian Institute of Science library in the early seventies. Neither during my engineering college days nor during my days as a graduate student had I heard of his remarkable achievements; nor did I ever come across him holding forth at a conference or hear of him at one of these. This quiet genius had done his work, single handed, and then simply disappeared from the scene making no claims for himself or his achievements. To those of us who prefer our heroes in the heroic mould of a previous age, when greatness was measured by what you had actually done, Whittle belongs, along with a few other loners of his generation like Bethune and Turing, in the first rank of these.

Sir Frank Whittle

Annual Review of Microbiology 1994. Nicholas Ornston, Albert Belows and E. Peter Greenberg, eds. Annual Reviews Inc., 4139 El Camino Way, Palo Alto, California, USA. Vol. 48. Price: \$139. 834 pp.

While it is late to review the 1994 issue of this series at this time, several articles in the issue drew my attention. The first and foremost was the opening article 'A Charmed Life' by Boris Magasanik, senior lecturer at MIT, Cambridge, MA, USA. I was influenced by one of Boris' chalk board presentations during an in-house symposium in the honour of H. G. Khorana at his retirement a couple of years ago. Hence, it was with great pleasure that I went through this article. Reading through his biography was a reminder of how careers of scientists of his time depended on the events of the World War II and, in his case he even had to serve in the US army in England and France for nearly four years. In spite of this, his scientific career has been very illustrious. Immediately after completion of the army services, he joined Chargaff's group at the Columbia University for his PhD to work on inositol metabolism and completed his degree in 1948. Just then Chargaff had begun his studies on the composition of nucleic acids, and Boris continued for one more year to work on chemical and enzymatic degradation of RNA before joining as faculty at the Harvard Medical School in 1949. Boris' alertness to the recent trends in scientific research helped him utilize the bacterial genetics to the best advantage in isolating a number of auxotrophic mutants of *Klebsiella aerogenes*, *Salmonella typhimurium* and *B. subtilis*. These mutants proved to be instrumental in his studies on inositol metabolism, purine and histidine biosynthesis and some earlier concepts on catabolite repression, both at the Harvard Medical School and later at MIT when he moved there in 1960. Subsequently these studies paved a way for him to study the elegant mechanism of regulation of expression of glutamine synthetase (*glnA*) by the regulatory proteins NRI (NtrC) and NRII (NtrB) in bacteria.

This volume of the Annual Reviews is also important in that it contains a good collection of articles on the unique biology of trypanosomes, a parasitic protozoan responsible for a number of dis-

eases in humans and domestic animals. Pays, Vanhamme and Berberof review the mechanisms of differential and stage-specific developmental gene expression of variant surface glycoproteins (VSGs) and procyclins responsible for antigenic variation in the host. These organisms are unique in that modulation of promoter activity does not play an important role in gene expression. Instead, gene rearrangements, change in chromatin structure, and various aspects of posttranscriptional and translational controls are mainly responsible for regulation of gene expression. Of particular interest to me was that the presence of a novel nucleotide, β -D-glucosylhydroxymethyluracil in the telomeric regions of the bloodstream forms correlated with the inactivation of expression sites possibly as a result of alterations in the chromatin structure. In bloodstream form, glycolysis is the major pathway used by the parasite for energy generation. Sommer and Wang have contributed an article that provides details on targeting of proteins to glycosomes (organelles that compartmentalize glycolytic enzymes). Detailed knowledge of targeting signals should prove useful in developing therapeutic reagents which can be targeted to glycosomes to inhibit glycolysis. *Trypanosoma brucei brucei* is infectious to domestic animals but it is rendered noninfectious in humans because of the presence of the cytolytic activity against this strain in normal human serum. However, this cytolytic activity does not restrict the disease-causing strains, *Trypanosoma brucei gambiense* and *Trypanosoma brucei rhodesiense*. High density lipoprotein (HDL) was characterized to be responsible for the lytic activity. Hajduc, Hager and Esko have reviewed the high density lipoprotein-mediated killing of the trypanosomes. Biochemical characterization suggests apolipoprotein A1 to be the active ingredient in this killing process. While the exact mechanism for the lytic activity of HDL/apolipoprotein A1 is not clear, various models that lead to internalization of HDL/apolipoprotein A1 and subsequent lysis of the parasite have been discussed. In any case, these observations could be very important in development of HDL-based therapeutic reagents against trypanosomes. Another aspect of trypanosome biochemistry on characterization of *trans*-sialidase (TS) has been described by Schenkman,

Eichinger, Pereira and Nussezeiw. This enzyme catalyses transfer of sialic acids from host glycoconjugates to acceptor molecules of the parasite plasma membrane. Interestingly, *T. cruzi* (causative agent for Chaga's disease) expresses this enzyme both in the insect vector and the human host whereas the African trypanosomes (causative agents of sleeping sickness) express this enzyme only when in the insect vectors. This enzyme has been characterized and its gene has also been cloned. This enzyme is important in that it performs glycosyl transfers without using a nucleoside diphosphate substrate. Yet another article by Zilberstein and Shapiro provides details on the role of the environmental factors such as pH and temperature on stage-specific gene regulation of a related genus, *Leishmania* responsible for various human diseases.

Feagin reviews on extrachromosomal DNAs of apicomplexan (sporozoa) parasites. Well-known examples of these protozoan parasites are the *Plasmodium* species. Other parasites that cause diseases in humans include *Toxoplasma gondii* and *Cryptosporidium* species. Several others such as *Babesia*, *Theileria* and *Eimeria* cause diseases of domestic animals. What is most interesting of the mitochondrial DNA in these organisms is the presence of the ribosomal RNA (rRNA) sequences in discontinuous regions resulting in fragmentation of the rRNAs. These fragments correspond to only the highly conserved regions of the rRNAs. Variable region sequences of the rRNAs have been dispensed with. This 'gene shrinking' experiment that the nature has performed should be extremely useful for structure function analysis of the rRNA.

Further, Gerhart, Wagner and Simons have contributed a review on the regulation of expression by antisense RNA in prokaryotes. The article is very informative and a good starting point to learn 'everything you wanted know but were afraid to ask' about how the copy number of various plasmids is regulated by antisense RNA. The chapter also describes the role of antisense RNA in regulation of bacteriophage and in Tn10 (Tet^R) gene expression. Conveniently, general aspects of both the later topics have been reviewed by Campbell and, Hillen and Berens, respectively in the same issue. The book also contains a chapter by Loewen and Hengge-Aronis

on regulation of prokaryotic gene expression by σ in the stationary phase of the growth.

In retrospect, the review on prion proteins by Prusiner turned out to be a remarkable and ahead of its time contribution. The article journeys through the chronological developments of how from total denial, it became an established fact that the protein molecule alone is the infectious agent which causes scrapie of sheep, bovine spongiform encephalopathy (BSE) of cattle and Creutzfeldt-Jacob disease (CJD), fatal familial insomnia (FFI), etc. of humans. It is striking that a conformational change of some α -helical regions of the prion protein to β -pleated sheets converts a normal protein into an infectious agent. With the recent outbreak of BSE in UK, this article will definitely be a thirst quencher to many curious biologists.

The book also includes reviews on many other infectious organisms such as mycoplasmas and their role as cofactors during HIV infection. Several articles have been devoted on the aspects of microbial physiology as well as on industrial production of economically important products. Overall, the editors – L. Nicholas Ornston, Albert Belows and E. Peter Greenberg – have put together a good collection of articles worthy of appreciation. Most certainly, one cannot go wrong in acquiring this book for a personal collection.

Dyke Swarms of Peninsular India. T. C. Devaraju ed. Geological Society of India, Bangalore. Memoir 33. 1995. 451 pp. Price: Rs 500, \$ 50.

Dyke swarms constitute an important feature of the earth's crust. These intrusive bodies represent major thermal and deformational events of the earth's long history and thus provide useful constraints to monitor the evolutionary processes leading to the development of crust and mantle. Like other shields of the world the Indian shield has also received voluminous amount of magmatic

material in the form of dykes and other shallow level intrusions at distinct time intervals. However, unlike other geological features, the dyke rocks of Indian Peninsula have not received due attention from geoscientists. Even details on their geological occurrence and distribution in time and space are lacking in the literature. The Geological Society of India, which has the reputation of bringing out monographs on such topics, has fulfilled a long-felt need of researchers working particularly in the field of petrology, geochemistry and tectonics which can provide up-to-date information on dyke rocks of peninsular India. Although a considerable amount of data in terms of geological occurrence, and major, trace and rare earth elements and also the isotopes are now available on their eruptive counterparts, the dyke rocks have generally been neglected. This monograph is an attempt to fill this gap for the benefit of researchers engaged in determination of chronology of geological events in peninsular India. The book covers not only some of the more significant features of dyke swarms of peninsular India, but also deals with some more important general aspects of dyke rocks.

The first three papers in the monograph are concerned with the review of research work done on general aspects of dyke rocks. These papers provide a good insight into some important features of dyke suites like flow and crystallization (by I. M. Platten), palaeomagnetism (by M. E. Evans) and clouding of feldspars (by H. C. Halls and Boaxing Zhang).

The next two papers deal with some general aspects of Precambrian dyke swarms of South Indian shield. On the basis of occurrence, distribution and age data, N. G. K. Murthy has identified five episodes of dyke activity ranging in age from 2240 m.y. to 75 m.y. A review of palaeomagnetic data on some dyke rocks of Indian shield is presented and discussed by V. Damodara Reddy *et al.*

The next three papers present case histories of some important Precambrian dyke swarms of southern Peninsula. Amitabha Sarkar and A. K. Mallik have discussed the isotopic and geochemical data to draw interpretations regarding age and petrogenesis of dykes of Kolar Gold Field. Two episodes of Proterozoic dyke activity are identified which the authors have tried to correlate with general dyke-forming events of Indian shield. T. Radhakrishna and J. Mathew have

presented a paper on mafic dyke swarm occurring in high-grade terrain of south India. Isotopic and geochemical data of advance nature are adequately used to interpret some important conclusions regarding evolution of Indian lithosphere. A detailed account of geochemical data on mineral phases of a dyke from Karnataka is presented by T. C. Devaraju and others for an understanding of differentiation processes.

A. B. Roy and others who have been authors/co-authors of some of the most informative papers on the Aravalli belt in the past, have contributed a paper on the dyke rocks of this region. The paper reveals seven dyke-forming events in Aravalli history. The occurrence of felsic dykes is of special significance. Another paper on dyke rocks of western Indian shield is by N. Kochhar and co-workers. These authors have presented the petrology and the geochemistry of acid and mafic dykes of Trans-Aravalli region associated with Jalor magmatic activity. This activity is considered to have been manifested in response to an abortive attempt of rifting in the Trans-Aravalli part of Indian lithosphere at about 750 m.y. ago.

The mafic dyke swarms of central Indian shield are dealt with in the paper by H. M. Ramachandra *et al.* The paper describes the occurrence of many dyke swarms in the region and provides details of Bhanupratappur–Keskul mafic dyke swarms. On the basis of field occurrence and geochemistry, the authors have discussed their petrogenesis and tectonic setting and find a close affinity of these dyke swarms with the famous Labrador and Scourie dyke swarms.

An interesting case history pertaining to dyke swarms of southern Karnataka is given by T. C. Devaraju and others in two papers. The authors have contributed 66 pages on these dyke swarms covering field characteristics, petrography, mineral chemistry, whole rock geochemistry and isotopic compositions. The data are adequately used to evaluate the relative significance of petrogenetic processes in the magmatic evolution of these dyke swarms and to interpret their tectonic setting.

J. Mallikarjuna Rao and others have discussed the field occurrence and K–Ar and Ar–Ar ages and geochemistry of dyke swarms related to Cuddapah basin and draw interpretations regarding their petrogenesis and tectonics. These

authors find an episodicity in Cuddapah magmatism between a period from 1850 to 1000 m.y., with a peak at about 1400–1100 m.y. However in another paper Y. J. Bhaskara Rao *et al.* have discussed their Rb–Sr age data on Pulivendla sill of Cuddapah basin. These authors have placed an 1800 m.y. age limit of a single major episode of mantle magmatism and Cuddapah basin formation.

The rest of the papers deal with various aspects of dykes and dyke swarms occurring along the western coast of India and Narmada rift, related with Deccan volcanism. K. B. Powar and S. V. Vadetwar discuss the geological occurrence, mineral chemistry and whole rock chemistry of dykes and plugs occurring in Revas–Murud area of Konkan coastal belt. The compositional variation from basaltic dolerite to gabbro-diorite is considered to be a consequence of fractional crystallization of a common magma. The status of these intrusives as feeders is rejected. S. F. Sethna and M. Mousavi present the major and trace element data on dykes and associated intrusions of Deccan basalts occurring on the western coast. These authors find influence of differentiation and crustal contamination on the chemistry of these rocks. Their derivation is interpreted in terms of batch partial melting of a heterogeneous mantle source. Another paper on the dyke rocks of western coast is by A. G. Desai and A. A. A. Viegas. The authors have identified four generations of dyke swarms which are related with tectonic evolution of western Indian continental margin.

A detailed account of field characteristics, structural setting, petrography and geochemistry of alkaline–tholeiite dykes associated with Amba Dongar and Phenai Mata complexes of lower Narmada valley is presented by L. G. Gwalani and others. R. V. Karanth and D. A. Sant have contributed on dyke swarms of southern Saurashtra. They have identified seven generations of dyke swarms which were emplaced along deep seated fractures related to Narmada rift zone.

Although the monograph covers almost all parts of Indian shield where current research is being carried out, there are certain important areas which are not represented. A glaring omission is Proterozoic dyke swarms of eastern Indian shield, i.e. the Newer Dolerites. It would have been better if a paper had

been included on these dyke rocks. The editor has done an admirable job by giving a summary in the beginning of the book with specific mention of the importance of dyke swarms in the studies of evolutionary history of crust and mantle, which is a real help to the reader. However, the absence of author and subject indices may be felt by the readers. The printing and get-up are good, size of letters is large enough but in some of the papers the size of diagrams particularly those of maps showing distribution of dykes is small.

Overall, the monograph is a welcome addition to the literature on Indian shield. The book, which contains a wealth of basic scientific data on dyke rocks of Indian shield, is worth possessing by any geoscientist.

M. RAZA

*Department of Geology,
Aligarh Muslim University,
Aligarh 202 002, India*

Annual Review of Astronomy and Astrophysics 1994. Vol. 32. Geoffrey Burbidge, ed. Annual Reviews Inc., 4139 El Camino Way, Palo Alto, California, USA. Price: USA \$ 60, elsewhere \$ 65. 662 pp.

This volume of *Annual Review of Astronomy and Astrophysics* contains fourteen articles covering a wide range of subjects from The Goldilocks problem: climatic evolution and long-term habitability of terrestrial planets to Baryonic dark matter and Recycled pulsars. All the topics are of great current interest and quite a few of them are relatively new areas of research. For example, the article by Brown and Gilliland on 'Astroseismology' is a first in the Annual Review series, although Deubner and Gough wrote on 'Helioseismology' more than a decade ago. During the last decade astroseismology has come of age and is providing a new way of looking at the interiors of stars. Brown and Gilliland's review is a very timely account of the progress in the field and of the promise it holds for the future. Similarly, the article 'Anisotropies in the Cosmic Microwave Background' could not have been written

much earlier as the observational breakthrough came only in 1992 with the first detection of large angular scale anisotropies of cosmological origin in CMB.

Much of the exciting progress in astronomy in the recent times has come about through advancements in technology, launch of new missions in space, commissioning of large ground-based optical telescopes (of aperture greater than 6 m), etc. Much of what has been reviewed in the volume carries the stamp of these developments. Infrared observations have revealed the existence of large quantities of very hot gas in clusters of galaxies. Refinements in radioastronomical techniques have led to accurate determination of isotopic and elemental abundances in the interstellar medium. Space missions have breathed new life into the studies of cosmic dusty plasmas. All of these subjects have been reviewed by respective experts in these fields. The references at the end of each of these articles with hardly any citations earlier than 1980 reveal how current the work reported on is.

While stellar physics absorbed the attention of the astronomers in the immediate post-war decades of this century, it is galaxies and their evolution which command the maximum interest in the current period. We now have the capability of routinely observing stars in other galaxies and more importantly we can observe them in the ultraviolet, the optical and the infrared. Comprehensive studies of stellar populations in other galaxies are now possible. Global properties of galaxies as a function of their morphological types are better understood. Deeper questions regarding the formation and evolution of stellar populations in galaxies can be addressed. Massive stars provide most of the light of the galaxies and the cooler stars most of the mass. The massive stellar population is best studied in the ultraviolet, the cooler red population in the near infrared. Panchromatic studies are therefore of great importance. The Hubble Space Telescope (HST) is providing spectacular pictures of external galaxies, starburst nuclei, quasars and their environment, distant clusters, etc. For the distant galaxies the light from the massive stars is redshifted and infrared observations (e.g. K band photometry) reveal many of the details that are usually seen in the optical observations of the nearby galaxies.

BOOK REVIEWS

Reviews by Roberts and Haynes (The Hubble sequence) and Maeder and Conti (Massive star populations in nearby galaxies) touch upon many of these crucial aspects of extragalactic studies.

Bigger than the galaxies and their clusters is the Universe itself and its origin and evolution occupy the attention of a very large number of theorists and observers. Today Physical Cosmology is an observational/experimental science in which definite physical models are used to interpret and predict the results of measurements. Results from the COBE satellite, from the HST key project to determine extragalactic distances to greater accuracy and from high resolution spectroscopy of faint distant galaxies with the Keck telescope have opened up hitherto inaccessible ways of investigating the cosmological problem. Many of the well-established notions of the Standard Big Bang Cosmology are being severely tested, the cosmological ques-

tions are being further sharpened. What is the age of the Universe? Is the Universe going to expand forever? How much of the matter in the Universe is in the dark form? How did galaxies form? When did they form? These and many other related questions are exercising the minds of the cosmologist, the astronomer and the particle physicist and a great debate is on. This volume 32 of the Annual Review brings us a flavour of these issues through the articles of Carr, White, Scott and Silk, Dekel and Fabian. There is a lot to ponder over and a lot to marvel at.

I shall be remiss if I do not mention the Prefatory Chapter of this volume. Margaret Burbidge is the author of it and her contribution 'Watcher of the skies' is a delight to read. Burbidge has been one of the distinguished astronomers of our times and the account of her life as a professional astronomer is of great common interest. As she says, the ARAA

Editorial Board invited her to write an account that would acquaint an observational astronomer today 'with what it was like to use optical telescopes before TV, 2-dimensional photon counting devices and computers'. She has succeeded in her job admirably. We now have in ARAA Prefatory Chapters accounts by three of the famous foursome B²FH.

Astronomy and astrophysics are a rapidly progressing field. Many of the results reviewed in this volume will either be improved upon or superseded by new developments in future. By monitoring this progress annually through superbly written articles, ARAA is doing a signal service to the astronomical community.

MEETINGS/SYMPOSIA/SEMINARS

National Seminar on Biotechnology: New Trends and Prospects

Date: 25-27 November 1996

Place: Hardwar

Themes include: Microbial preparations and plant products; Education and research in biotechnology- Indian priorities; Microbial technology and renewable energy; Biotechnology for agriculture; Biotechnology in health care and food biotechnology.

Contact: Prof. D. K. Maheshwari
Convenor
Unit in Microbiology, Department of Botany
Gurukul Kangri University
Hardwar 249 404
Phone: 427871

National Symposium on Environment III: 1996. Eco-friendly and Biorational Pollution Management in Soil, Water and Air

Date: 10-12 December 1996

Place: Pune

The above seminar will be held in Hindi at National Chemical Laboratory, Pune. Themes: a) Pesticides: Alternatives - plant products, IPM, biopesticides etc.; b) Industrial effluents; c) Early warning systems: Role of biomonitoring; d) Miscellaneous.

Contact: Dr R. N. Sharma
Convenor, Head, Entomology
National Chemical Laboratory
Pune 411 008
Phone: 336451; Telex: 014-66,586
Fax: 335153, 330233

Edited and published by Prof. P. Balaram and Prof. S. Ramaseshan, Current Science Association, Bangalore 560 080.
Typeset by R D Typesetters, Bangalore 560 010. Printed by Lotus Printers, Bangalore (Ph: 3380167).

Current Science, founded in 1932, is published by the Current Science Association in collaboration with the Indian Academy of Sciences. The journal is also intended as a medium for communication and discussion of important issues that concern science and scientific activity. All articles published in *Current Science*, especially editorials, opinions and commentaries, letters and book reviews, are deemed to reflect the individual views of the authors and not the official points of view, either of the Current Science Association or of the Indian Academy of Sciences.

INFORMATION FOR CONTRIBUTORS

GENERAL

All manuscripts should be addressed to the Editor, *Current Science*, P. B. No. 8001, C. V. Raman Avenue, Bangalore 560 080. Submission of an article will be held to imply that it has not been previously published and is not under consideration for publication elsewhere; and further, that if accepted, it will not be published elsewhere. *Three copies of contributions of all categories* are required, with a letter of transmittal giving (i) names and complete addresses of the authors and (ii) title of the contribution and the category in which it is submitted (see below).

Current Science is a multidisciplinary journal and therefore research and review papers of general significance that are written clearly and well organized will be given preference. All papers will be first assessed by a Reviewing Editor. Papers found unsuitable in terms of the overall requirements of the journal will be returned to the authors. The others will be sent for detailed review. *Both solicited and unsolicited material will be reviewed.* Authors of these papers will be notified of acceptance, rejection, or need for revision of the paper. Returned papers cannot be resubmitted. Illustrations and other material to be reproduced from other publications must be properly credited; it is the authors' responsibility to obtain permission for reproduction (copies of letters of permission should be sent).

CATEGORIES OF MANUSCRIPT

General articles (not exceeding 5000 words) discuss current trends in research in a field that will be of interest to readers outside the field; interdisciplinary topics: science policy and administration; or some aspect of the application of science and technology to human needs or the impact of science and technology on society/ecosystems/life. They should include a summary not exceeding 100 words, introductory paragraph(s), brief subheads at appropriate places to point to what follows, illustrations that will help a general reader, and references.

Review articles (not exceeding 5000 words) are expected to survey and discuss recent developments in a field. They should be well focused and organized, and avoid a general, 'textbook' style.

Research articles (not exceeding 4000 words) should report research results of fairly major significance. They should include an abstract not exceeding 100 words, introductory paragraph(s), and brief subheads.

Research communications (not exceeding 2000 words) should contain important findings that are novel and of fairly broad interest. They should include a brief abstract and an introductory paragraph. Text should not be broken up under subheads.

Correspondence includes letters, not exceeding 500 words, that are of general interest to scientists. All letters cannot be published.

Scientific correspondence contains technical comments, including those on articles or communications published in *Current Science* within the previous six months. Letters may be reviewed and edited.

Research news articles are intended to inform nonspecialists about recently published advances or important findings discussed at a meeting. Authors should also send a copy of the paper(s) on which the article is based. Meeting reports should avoid merely listing brief accounts of topics discussed, and must convey to readers the significance of an important advance.

Research accounts articles are intended to be personalized reviews of research from the authors' own laboratory, based on a body of published work. The articles must provide appropriate background to the area in a concise introduction, which should also serve to place the author's work in proper perspective. Articles will normally

not exceed 8 to 10 printed pages.

Opinion articles present views on issues related to science and scientific activity. **Commentary** articles should contain expository notes on issues related to science and scientific activity.

Book reviews. Unsolicited reviews will also be considered. Reviews that merely 'list' brief descriptions of the contents cannot be published. Reviews should have 'context' and convey some information about the subject of the book.

Historical commentary and notes inform readers about interesting aspects of personalities or institutions of science or about watershed events in the history/development of science; most are expected to relate to India. Illustrations are welcome. Brief items will also be considered.

MANUSCRIPT PREPARATION

Manuscripts should be typed double-spaced on one side of white bond paper (21×28 cm). The pages should be numbered consecutively, starting with the title page and through the text, reference list, tables and figure legends. The title should be brief, specific and amenable to indexing. Not more than five **keywords** should be indicated separately; these should be chosen carefully and must not be phrases of several words. **Summary** and **abstract** should not have more than 100 words and should convey the main point of the paper, outline the results and conclusions, and explain the significance of the results.

Text. All papers should have a brief introduction. The text should be intelligible to readers in different disciplines and technical terms should be defined. Tables and figures should be referred to in numerical order. All **symbols** and **abbreviations** must be defined, and used only when absolutely necessary. Superscripts and subscripts and ambiguous characters should be clearly indicated. **Units of measure** should be metric or, preferably, SI. Methods should, as far as possible, be described briefly in appropriate table and figure legends.

Figures. In the case of line drawings one set of originals (without any lettering) is sufficient, with two copies containing lettering. In the case of photographs good prints are required with each copy of the manuscript; photocopies are not acceptable. Line drawings should be roughly twice the final printed size. The correct orientation should be indicated if not clear.

Photomicrographs and other photographs that require it must have a scale bar, which should be defined clearly in the legend. Primary data should be submitted as far as possible (e.g. actual photographs of electrophoretic gels rather than idealized diagrams).

References should be numbered in the order in which they appear, first through the text and then through table and figure legends. The following are examples of ways of writing references.

1. Mukundan, T. and Kishore, K., *Curr. Sci.*, 1991, 60, 355-362.
2. Constantine, G., in *Biology of Bats* (ed. Wimsatt, W. A.), Academic Press, New York, 1970, vol. 1, pp. 319-322.

Acknowledgements should be brief. Footnotes are not allowed except to identify the corresponding author if not the first.

Cover photographs. Good photographs (colour or black and white) that pertain to a submitted paper will be considered for use on the cover. Good *prints* and a legend should be submitted with the manuscript. In the case of a colour picture, a transparency will be required for printing if accepted.

PROOFS AND PUBLICATION

Two sets of galley proofs are sent to the corresponding author. A reprint order form accompanies the proofs.

COVER. The first Indian high-yielding variety, Jaya, released in 1968 for cultivation in irrigated ecosystems. Jaya immediately claimed nation-wide patronage from farmers. See page 438.

Indexed in CURRENT CONTENTS/GEOTitles/CHEMICAL ABSTRACTS

In this issue

Quinine sensitization

Ever since Jesuit priests discovered the anti-malarial properties of the cinchona bark, quinine has been used as a therapeutic for treatment of malaria and as a prophylactic in endemic areas. Although displaced in recent times by synthetic antimalarials, quinine is still important in view of the increased incidence of drug-resistant *Plasmodium* infections, treatment of which will eventually require the availability of diverse therapeutics.

Commenting on a paper published earlier in *Current Science* (Talwar *et al.* 1995, 68, 437-440), Sharma (page 430, this issue) raises an important question on the advisability of using quinine in contraceptive cream formulations and more generally for non-therapeutic purposes. The case of the 'blackwater fever' syndrome is highlighted, where quinine 'sensitized erythrocytes' may become targets for immune attack following *Plasmodium falciparum* infection. Sharma's letter should focus attention on the need to enhance the range of available tools for checking the spread of malaria and more importantly, to consider courses of action for the future, when drug resistance will undoubtedly become a major public health issue. In his response Talwar (page 431) notes that the more recent polyherbal cream formulations contain no quinine at all.

P. Balaram

Calories and longevity

Should one eat less? The answer would appear to be an emphatic yes, if the decision were to be based only on the results reported by Subba Rao *et al.* (page 464). The authors draw an interesting correlation between calorie intake and DNA repair enzyme activities in groups of 'normal' and 'undernourished' human subjects. Diminished consumption appears to result in higher repair enzyme activities (in peripheral lymphocytes), as compared to the control group. Since DNA repair mechanisms are critical for survival of cells and organisms, there have been earlier claims that life span may be related to the capacity to repair DNA damage. This study extends to humans, earlier conclusions based on studies of experimental animals.

P. Balaram

Palaeolake implications

Sediments of the old and the now vanished lakes formed in the later Quaternary epochs unfold eloquent records of the climate changes and the tectonic upheavals that overtook the land 50,000 to 40,000 years ago. The information these palaeolakes provide is valuable for understanding the trend of change in climate and the nature and pat-

tern of earthquakes and resultant landslides. By determining the recurrence intervals of catastrophic natural phenomena, it is possible to attempt prediction of hazards.

T. N. Bagati and his associates (page 479) describe a palaeolake nestling 3600 m above sea level on the northern flank of the Himalaya (Zaskar Range), close to the geological junction of the Indian and Asian continents. They show that the lake originated 45,000 years ago, practically in the same period when many existing and palaeolakes were formed in the Spiti basin in north-eastern Himachal and in Kumaun in the central sector of the Himalaya mountain; as the studies of our group demonstrated. Significantly, the Ladakh lake, like the lakes of Kumaun, evolved as a result of ponding of rivers following tectonic movements of appreciable severity. Another important finding is that the presence of charcoal in the lake sediments, like those of the Kumaun lakes, indicates forest fires resulting presumably from lightning. It seems that forests in dry warm climate caught fire all over the Himalayan domain. The development of warm climatic condition is substantiated by magnetic susceptibility studies. It seems that the whole of the north-western Himalaya was rocked by major earthquakes and attendant hazards some 45,000 years ago.

SUBMISSION IN ELECTRONIC FORM

Authors who have been informed of acceptance of their manuscripts may send the final, accepted version of the manuscript in electronic form on floppy diskette (3.5" preferred; IBM PC format only, *not* Macintosh). The text of the manuscript only should be supplied as a plain ASCII file with no formatting other than line and paragraph breaks. (Wordstar 5.5 or 7.0 and Microsoft Word for Windows 6.0 are acceptable, but ASCII is preferred). A hard copy of the text, with all typesetting information (italics, bold, mathematical type, superscripts and subscripts, etc.) must accompany the electronic copy. Tables and figures must be supplied only as hard copy. The diskette must be labelled clearly with the following: manuscript number, file name, file information (ASCII or Wordstar, version number, etc.)

Text may also be transmitted as ASCII only by e-mail to currsci@ias.ernet.in.

We expect that electronic submission will result in quicker processing for publication.

CORRESPONDENCE

Indian journals: To start or scrap?

It is a matter of shame that we tend to publish our findings in foreign journals to get better citation ratings and recognition. It is high time a national consensus was evolved on amalgamating different 'obscure' (*sic*) research journals to form one Indian journal of international standard and repute. This is very essential in the Indian context, notwithstanding the global trend to start highly specialized journals (e.g. *Tissue Engineering*). In India too, university-based journals have bloomed to bridge the scientific community with academia (e.g. *Resonance* from Bangalore) and industries (e.g. *Curie* from Pilani). These journals cater to specific needs at

various levels, and do not fall under the aforesaid category that requires unification.

It is sad to learn that the UGC has decided to abandon for good one such popular science journal, *Chemistry Education*. I have been associated with this journal in two ways: (i) To get handy up-to-date reviews/research information on various aspects of chemistry, during my master's programme at BITS. (ii) As a contributor myself (*Chem. Ed.*, 1995, 12, 19-23).

The editorial board comprised of illustrious names like C. N. R. Rao, D. Balasubramanian, etc. The journal was serving its pedagogic purpose only

too well when the decision to close down has come from the UGC. Considering its immense utility as a supplementary text to University students and instructors, the UGC is urged to continue sponsoring *Chemistry Education*.

Microbes, molecular biology and the final assault

V. Ramalingaswami's excellent article¹ aptly highlights the infectious disease scenario in the changing world and ends with an optimistic note on the 'art of the possible'. The major instrument for the 'art of the possible' here, obviously, is molecular biology which is increasingly being applied to unravel the molecular underpinnings of the microbial pathogenicity^{2,3}, diagnosis of infectious diseases⁴ and development of newer therapeutic and prophylactic interventions especially novel vaccines. The benefits accruing from these developments would be enormous, but going by their versatility the pathogenic microbes are capable of outwitting all interventional strategies. My obvious reference

is to problems like emergence of new infections⁵, antibiotic resistance and antigenic variations among microbial pathogens. In addition to these problems, extreme complexity of molecular mechanisms underlying microbial pathogenicity puts molecular biologists on an extremely uphill task. Molecular biology as applied to infectious diseases thus needs further impetus. It is probably in this context that Cold Spring Harbor Laboratory⁶ is organizing a meet, later this year, on 'Molecular Approaches to Control Infectious Diseases'. The topics for discussion include - bacterial, parasitic and viral vaccines, HIV/SIV, DNA immunization, immunogenic structures and emerging infections.

Another area which needs particular attention in our endeavours to combat infectious diseases is their epidemiology. In fact, over the years epidemiology has become one of the most neglected aspects of the control of infectious diseases - a fact even acknowledged by CDC⁷, which keeps a tab on the outbreaks of epidemics and emergence of newer infections worldwide. However, recently, European disease-control organizations have joined hands to form surveillance networks to monitor important infectious diseases. CDC is also trying to establish more links across the Atlantic and the Pacific⁷.

To focus attention on the emerging and re-emerging infections, there is a

CORRESPONDENCE

worldwide collaboration among various medical journals in which some of these journals are devoting entire issues to this topic⁸. CDC has even started publishing a journal, *Emerging Infectious Diseases*, to provide peer-reviewed information on emerging microbial pathogens and related issues⁹.

Echoing Ramalingaswami's sentiments – allowing one the luxury of a vision – with further impetus to research on the molecular approaches to the control of the infectious diseases and reinforcement of epidemiological studies, it may be possible to mount a final assault on the conquest of the infectious diseases.

The aroma of *Bassia* flower

In an earlier publication (*Curr. Sci.*, 1996, **71**, 257) it was mentioned that 2-acetyl-1-pyrroline (2AP), the aroma molecule of basmati rice and tiger marking fluid may also occur in the flowers of *Bassia latifolia*.

We have now confirmed this with HPLC. 2AP from fresh flowers was extracted as citrate, eluted by paper chromatography and run in HPLC together with standard 2AP-citrate. 2AP occurs in fresh *Bassia* flowers

in relatively large quantities.

SCIENTIFIC CORRESPONDENCE

Praneem polyherbal cream for contraception – Safety in malaria endemic countries

WHO reports worldwide 300–500 million clinical cases of malaria, and 1.5 to 2.7 million deaths each year, and about 40% of the world's population is at risk in some 90 countries¹. In India, malaria cases fluctuate between 2 and 2.5 million, and *Plasmodium falciparum* constitutes about 1 million or 40% cases annually. *P. falciparum* is found in almost all parts of the country, but it is a predominant infection in the north-eastern states, Orissa and the forested and irrigated tracts in peninsular India². Furthermore, *P. falciparum* has become resistant to anti-malarial drugs so that recrudescences are more common³.

Praneem polyherbal cream and pessaries with dual properties of contraception and alleviation of genital infections by G. P. Talwar *et al.* have completed phase I clinical trials at the Safdarjung Hospital, New Delhi⁴. It seems to have a go-ahead signal. Praneem polyherbal cream contains purified extract of neem seeds (praneem), quinine hydrochloride and saponins from reetha (*Sapindus mukerossi*), dispensed in a water-soluble cream base. We are concerned at the quinine hydrochloride content in the praneem polyherbal cream which constitutes 30 mg/ml. The recommended dos-

age is 5 ml of the cream each time, i.e. 150 mg quinine hydrochloride.

Classical blackwater fever (BWF) syndrome occurred predominantly in the non-immunes or semi-immune people exposed to falciparum malaria who were taking quinine in an irregular fashion as a prophylactic. BWF used to be a common malaria complication in endemic countries, but with the advent of synthetic anti-malarial drugs such as proguanil and chloroquine, BWF has become extremely rare⁵, although sporadic cases of BWF have now been reported after halofantrine and mefloquine treatment^{6–8}.

Praneem polyherbal cream contraception technology is likely to result in the (i) loss of sensitivity of the malarial parasite to quinine as a result of its low levels in populations⁹ and (ii) polyherbal contraception may trigger immune reaction against drug-sensitized erythrocytes so that people contracting *P. falciparum* infection may come down with BWF, a serious condition characterized by massive intravascular haemolysis leading to anuria and renal failure^{5,8}. At a time when malaria is returning with speed and available malaria control tools have started producing diminishing returns, use of quinine for other than therapeutic purposes may be hazardous.

one employed for contraception has no quinine hydrochloride (QHCl). Thus the risk, howsoever small, of developing resistance to quinine is not posed.

In reading the results of the experiment reported in Table 1 of the cited paper, Sharma has however, wrongly interpreted the concentrations of QHCl used in the initial prototype formulation. 30 mg/ml was the stock solution, which was tested at various dilutions to determine the dilution at which complete spermicidal action is obtained. In column 3 of the table, it is clearly reported as 3.46 ± 0.30 mg/ml (mean was taken as semen from 10 healthy donors was evaluated). It is not 30 mg/ml, the figure on which Sharma has made projections.

A new international order on oceans – Indian perspective

M. Sudhakar and B. V. Kumar

The arduous work of the League of Nations for a decade (1973 to 1982) to finalize the text that contained provisions to protect the larger interests of the developing nations has been realized with the coming into force of the Third United Conference on the Law of the Sea on 16 November, 1994. A brief account of the history and enumeration of the events and articles, is attempted here. Recognizing the need to conform to the international law, being a major role player in the very evolution of the new international order of oceans, India amended its Constitution enacting the Maritime Zones Act, in 1976. Realizing that oceans are the next 'techno-strategic frontier' to Atomic Energy and Space, India developed a large institutional framework and launched various challenging programmes at sea, on par with other leading nations on the oceans. The living and non-living resources potential within the country's maritime zones, are discussed.

In the course of time, man is looking more and more towards the sea for substitute material and food. It was believed that a situation would arise wherein the vast expanse of oceans covering 70 per cent of the earth's surface, would be divided into lakes and the more powerful nations would have an unhealthy hold over most of these areas, which are the repositories of both living and non-living resources, that could meet the demands of the world's growing population and rapid industrialization of the developing nations. After the Second World War, mankind realized the importance of a code to regulate the uses of the sea for peaceful and developmental purposes. Although unknown to many, the United Nations made a remarkable achievement in the history of mankind, when the Third United Nations Convention on the Law of the Sea (UNCLOS-III) came into force on November 16, 1994, one year after Guyana brought the total number of ratifications to the required sixty¹.

United Nations Law of the Sea – Retrospect and Prospect

When the League of Nations was replaced by the United Nations in 1945, it was thought desirable to provide for the establishment of a body, i.e. the International Law Commission (ILC) charged with the progressive codification of the International Law of the Sea. ILC submitted a report in 1956 to the UN, which formed the basis for the first UN Conference on the Law of the Sea (UNCLOS-I) held at Geneva, in 1958.

The UNCLOS-I produced a legal framework of rules governing States rights and duties in the Territorial Sea, Continental Shelf and High Seas. UNCLOS-I had adopted four conventions: The convention on the Territorial Sea and the Contiguous Zone; The convention on the High Seas; The convention on the Continental Shelf and a convention on the Fisheries and Conservation of Living Resources of the High Seas. The first three of these have been ratified by a substantial number of States and are based mainly on the customary International Law, as presented in the ILC's report. Consequently, these conventions formed the core of the generally-accepted rules of the Law of the Sea concerning maritime zones.

The major problem which UNCLOS-I faced was to agree on some definite outer limits for the Territorial Sea. Unilateral assertions of coastal states further and further seaward, followed almost immediately; and the interest of naval powers and distant-water fishing nations was aroused. To overcome this, an UNCLOS II was convened in 1960 to discuss the problem, and also the associated question of fishery limits. It failed by only one vote to adopt a compromise formula providing for a six mile Territorial Sea plus a six mile Fishery Zone.

It was agreed in 1970, in the UN General Assembly to convene a third UN Conference, with the task of producing a comprehensive convention on the Law of the Sea (UNCLOS-III). UNCLOS-III had to negotiate a political package that would be acceptable to all States. It had its origin in the Seabed Committee, established in 1967, by the UN General Assembly at the initiative of the then Maltese Ambassador, Arvid Pardo, to examine the implications of a declaration that the deep sea bed lying

The authors are in the Geological Oceanography Division, National Institute of Oceanography, Dona Paula, Goa 403 004, India.

beyond the limits of national jurisdiction is a 'Common Heritage of Mankind'. This involved defining the limits of national jurisdiction, over the sea bed and, therefore, the revision of parts of UNCLOS-I on the Continental Shelf, as well as on the High Seas.

After extensive work spanning about a decade (1973 to 1982), UNCLOS-III was opened for signature in Montego Bay, Jamaica, on December 10, 1982; and was signed by 117 States including India, on the same day. By December 9, 1984, it was signed by 155 States and 4 Entities. UNCLOS-III Regime could not come into force for more than a decade after the Convention was opened for signature. The reasons were many. The main objection came from countries such as the USA, UK, Germany, and other industrialized States; who opposed many of the provisions on seabed mining in international waters (Part XI of UNCLOS-III (ref. 2)). Further, the poor prospects of commercial production of seabed minerals and the lack of economic necessity were the other reasons, for non-implementation of UNCLOS-III.

The Preparatory Commission (PrepCom) was established in 1982 (as per Resolution-I) pending coming into force of the UNCLOS-III. It made commendable progress between 1983 and 1993 and provided a number of fair and viable solutions to the seabed provisions of UNCLOS III. The PrepCom efforts have culminated in a progressive ratification during the last few years, and resulted in the UN Convention on the Law of the Sea (UNCLOS III, 1982) coming into force. On 16 November 1993, the sixtieth instrument of ratification was deposited with the Secretary General United Nations; and the Convention came into force exactly 12 months after, which has a bearing on all States party to it from the midnight of 15 November, 1994.

UNCLOS III (ref. 2) envisages nine different maritime zones with defined and distinct legal status for each zone. The major maritime zones involved in Law of the Sea are shown in Figure 1. Starting from the coast, the nine maritime zones are: Internal Waters; a 12 nm Territorial Sea, a 24 nm Contiguous Zone; a 200 nm EEZ; a Continental Shelf, extending up to the outer edge of the Continental Margin, with outer limits specified; the High Seas beyond the EEZ; the International Seabed Area, beyond the outer limits of the Continental Shelf; Archipelagic Waters; Archipelagic Sealandes; and the Straits used for international navigation. Thus, it seeks to delimit the oceans into a number of maritime zones based on its distance from the shore. The convention also deals with the baselines from which most of these maritime zones are to be measured.

Special provisions were made for the land-locked and geographically disadvantaged countries. Detailed provisions and safeguards on marine environment, marine scientific research, development and transfer of marine technology, and settlement of disputes; are the highlights and new concepts in the Convention. In the wake

Figure 1. Major maritime zones involved in the Law of the Sea.

of UNCLOS-III coming into force, two UN organizations shall be established, viz. the International Seabed Authority (ISBA) with its Headquarters in Jamaica, to organize and control activities in the seabed area beyond the EEZ, and, the International Tribunal for the Law of the Sea (ITLOS) at Hamburg in Germany to settle the disputes related to Sea.

Every coastal state is entitled to claim these maritime zones. It has sovereignty over the internal waters (i.e. the waters landward of the baselines) subject to innocent passage traditionally used therein; sovereignty in the Territorial Sea and the air above, with the right of innocent passage enjoyed therein by all foreign ships; specific rights in respect of customs, fiscal, immigration and health matters, in the Contiguous Zone, sovereign rights over the living and non-living resources and economic uses of the EEZ, and jurisdiction over marine installations, marine scientific research, and marine environment; sovereign rights over the natural resources of the continental shelf, including sedentary living resources and jurisdiction over certain specified matters.

The High Seas is beyond the jurisdictional limits of Coastal States and is a part of International Waters and in this zone the freedom enjoyed by all is, navigation, overflight, laying of submarine cables and pipelines, construction of artificial islands and installations, and fishing. The seabed under High Seas is the International Seabed Area, and for this, an elaborate regime and an international set-up is provided for in Part XI of the Convention. The International Seabed Area and its resources are the common heritage of mankind and their exploration and exploitation is to be regulated by the Convention.

The Convention lays down that the de-limitation of maritime boundary between States with opposite or ad-

GENERAL ARTICLES

jacent coasts, shall be in accordance with the median line-cum-special circumstances/historic title role concerning the territorial sea and on the basis of international law in order to achieve an equitable solution in respect of the EEZ and the Continental Shelf.

The Archipelagic State will have sovereignty over its archipelagic waters, with archipelagic sea lanes passage in traditional navigation Straits and innocent passage elsewhere. Like other coastal States, an archipelagic State is also entitled to other maritime zones.

There are other special and specific provisions for the land-locked States, whose right of access to and from the sea, and freedom to transit, is recognized. The land-locked and the geographically disadvantaged States have been given access to the surplus fishery resources of the EEZ in the neighbouring coastal State of the region, and for the conduct of marine scientific research.

A large majority of Coastal States conform to the provisions made in UNCLOS-III on various sea uses and resource utilization and have proclaimed their right to manage and control access to the resources and the use of the sea, and the seabed, up to a distance of 200 nautical miles from their coastlines. Coastal States are also extending their jurisdiction to the same distance in so far as environmental pollution, control of shipping, including supervision of dangerous cargoes and general problems of safety are concerned.

Establishment of International Seabed Authority

The International Seabed Authority situated in Jamaica, is seen in operation, when the UNCLOS came into force on 16 November 1994. Since that time, over two years ago, twenty-five additional states have ratified the Convention¹ (Table 1). India, having ratified the Convention on 29 July 1995, got involved in arduous deliberations and negotiations since then for a place in the Council of the ISBA. A high-level team, headed by A. E. Muthunayagam, had intense negotiations during the State Parties meeting held in New York from March 4 to 8 and again during the first part of the second session of the ISBA at Kingston, Jamaica, beginning March 11 (ref 3). The delegation staked a claim for India under the investor's category based on the country's various plans and activities at sea, particularly the investments made in long-term programmes like 'Polymetallic Nodule Surveys' in the Central Indian Basin, that brought distinction amongst the other developing nations. The election on March 18 entitled India to be a member of the Council for eight years, in two phases – first, for a two-year term from the current year and the next for four years beginning in the year 2000 (ref. 3). The Council consists of 36 members of the Authority elected by the Assembly, the sole and supreme organ of the Authority

*Information on ratifications was provided by the United Nations Division of Ocean Affairs and Law of the Sea in New York.

consisting of all the members¹. India had staked a claim and got a seat under the pioneer investor's category based on its various plans and programmes in seabed regime, and the preparatory investments made in polymetallic nodules, which registered India as the Pioneer Investor, with a Pioneer Area in the Indian Ocean. The other competitors for this category were USA, Russia, Japan, Germany, China, France and The Netherlands. China, France and Germany were elected to the Council under the investors' category³.

Establishment of Department of Ocean Development

After Atomic Energy and Space, the Oceans are India's next 'techno-strategic frontier'. Recognizing this, India made commendable progress in developing institutional framework for ocean management since 1978. A Department of Environment was established in 1980. Soon after, appreciating the importance of the ocean sciences, a need was felt by the then Prime Minister Indira Gandhi appreciating the importance of the ocean sciences, to establish a separate department to deal with oceanographic affairs, in the wake of UNCLOS-III coming for

signature. As a result, the Department of Ocean Development (DOD) was established in July, 1981, with the aim of creating a deeper understanding of the oceanic regime of the Northern and Central Indian Ocean and also development of technology and technological aids for harnessing of resources and understanding of various physical, chemical and biological processes. The Ocean Policy was enunciated in 1982.

In order to fulfil the objectives in the Ocean Policy, the Department has been promoting and implementing the following major research and development programmes:

- * Scientific research in Antarctica
- * Exploration and development of technology for exploitation of deep sea bed polymetallic nodules
- * Assessment of living and non-living resources
- * Programmes relating to coastal zone and islands
- * Marine scientific research and development of specialized manpower
- * Development of marine instrumentation and systems
- * Policy relating to Law of the Sea.

Indian perspective

Peninsular India is bestowed with a long coastline of about 7500 km along the Arabian Sea in the West, and the Bay of Bengal in the East, which opens into the

Indian Ocean in the South. It has over 1200 islands comprising the Andaman and Nicobar in the East and Lakshadweep in the Southwest.

A traditionally maritime country, with varied interests in the sea, especially in fisheries, oil and gas, shipping, seabed mining, power generation, protection of marine environment and national security, India participated effectively in UNCLOS-I (1958), UNCLOS-II (1960) and UNCLOS-III (1973–1982). It has amended the Constitution and enacted the Maritime Zones Act in 1976, the Coast Guard Act in 1978, the Maritime Zones of India Act for Regulation of Fishing by Foreign Vessels in 1981; and issued rules in 1982, and the Environmental Protection Act in 1986. Thus, the present Indian legislation on maritime zones largely conforms to the international law. The country has well demarcated and distinct maritime zones such as a 12 nautical mile Territorial Sea, a 24 nm contiguous zone, a 200 nm EEZ, the Continental Shelf that may extend beyond 200 nm (to be demarcated), and a Pioneer Area in the international seabed area for exploitation of polymetallic nodules.

By the year 2000 AD, the Indian population is estimated to be 1021 million, constituting about 16 per cent of an estimated world population of 6351 million⁴. The demand for minerals rises with the population explosion and rapid industrialization. India's demand for mineral resources is expected to increase two to threefold. The growing demand by the turn of the century for some metals awakes in us the desire for further discoveries

Figure 2. Map showing the Exclusive Economic Zone (EEZ) of India.

GENERAL ARTICLES

and investments. In addition, the production cost is likely to increase with energy prices and may make some low-grade mineral deposits uneconomical to mine on land. A growing need to look for new deposits of minerals at sea, is felt.

India gains a little over 2 million square kilometres of area under the EEZ regime (Figure 2), and this is equivalent to about two-thirds its landmass. In this area, the exclusive right to utilize living and non-living resources vests with our nation. The seafloor of the continental margins of India is covered by a wide variety of non-living resources. In addition to the vast deposits of offshore sand and gravel mainly used for road and building works, heavy mineral placer deposits containing ilmenite, magnetite, monazite, zircon, and rutile are located and exploited on many beaches and shallow waters along the coasts of Maharashtra, Kerala, Tamil Nadu, Andhra Pradesh, and Orissa. The National Institute of Oceanography (NIO), Goa, carried out exploration for ilmenite placer deposits in the Konkan coast extending offshore to a distance of 2 to 8 km at 18 to 20 m water depth and the estimated reserves are more than 12.5 million tonnes⁴.

Biogenic sediments containing offshore limeshells and sand deposits are investigated from shallow waters of the Laccadive islands (712 million tonnes) and the Gulf of Kutch (2 million tonnes), the outer shelf of Bombay and the Backwaters of Kerala (3 million tonnes)⁴. These deposits can be used by the cement, lime, glass, paper and chemical industries. Efforts are being made to identify the rich deposits of phosphorites along the Western Continental Shelf of India. Phosphorite exploitation from the offshore would make India self-sufficient in producing the raw material for the fertilizer industry. The offshore oil and gas scenario is positive. India's offshore oil and gas has overtaken the land production and supply, and is now double that of the land production. Under the new economic policy the Government of India invited bids for oil exploration in offshore blocks of Bombay, Cauvery Basin and the Krishna-Godavari Basin. Thus, India may enter into joint ventures with foreign companies in the form of production-sharing contracts. A joint venture between British Gas and the Gas Authority of India Ltd (GAIL) is a positive step towards offshore gas development for use in power generation and fertilizer industries. The variety and vast deposits available in our vicinity form a part of our resource, under the new international regime as stipulated in UNCLOS III. India has both sovereign rights and jurisdiction over these resources under the provisions of UNCLOS III.

On the living resource front, India's marine fish catch has been increasing since the declaration of its EEZ in 1977. The annual fish production in the country has touched an estimated 4.78 million tonnes in 1994-95 with the marine catch accounting for 2.69 million tonnes

inland catch reaching 2.09 million tonnes. Against the present estimates of maximum sustainable yield in the EEZ of 3.9 million tonnes, the fish catch accounts for only 70 per cent of the potential. It is, therefore, evident that there is scope for exploitation of the country's EEZ to achieve higher levels of production. In the 50 m depth, about 90 per cent of the assessed potential of 2.28 million tonnes is currently exploited, leaving limited untapped potential. But in depths beyond 50 m, exploitation is only at 40% level, leaving substantial scope for increasing the efforts⁵.

The Fisheries Panel Against Permitting Foreign Vessels, produced a draft National Fisheries Policy, which is awaiting Parliamentary approval. It is against permitting joint venture foreign vessels to fish in the EEZ of the country. The policy which was drafted by an Expert Committee and approved by the Central Board of Fisheries, wants the Government to empower more traditional fishermen to own mechanized boats that would go into the deeper waters for fishing, both surface and bottom dwelling species. Yet India has protected the interests of artisanal fishermen by reserving the 10 km area from the shore and between 10 and 23 km reserved for mechanized fishing vessels and beyond 23 km to be exploited by the industrial fishing vessels. This measure is meant to lower the pressure on the nearshore fishery resources targetted by all country-boats using traditional fishermen. The National Fisheries Policy is aimed at raising the fish production to enable a per capita consumption of 11 kg per annum as against 8 kg per annum at present, during the 9th Plan. It also aims at conservation of aquatic resources and genetic diversity⁵.

The traditional fisherfolk comprise about 2 million population along the coastal belts and they spend most of their lives in fishing. Fishing exports, particularly shrimps exports to Europe, Japan and USA, fetch about 1500 crores in foreign exchange. India is making efforts to develop aquaculture and the Indian Ocean Tuna catch. With assistance from World Bank and the United Nations Development Programme (UNDP), extensive hatcheries are planned throughout the country to distribute seeds for aquaculture development. India is actively involved in developing technologies for aquaculture, cage culture, mussel culture and in the use of satellite remote sensing for locating fish schools in an effort to assist the fishermen in improving their fish catch.

India made a claim in another maritime boundary, too. It made a claim in the International Seabed area for the development and exploitation of mineral resource, viz. 'polymetallic nodules'. Polymetallic nodules, commonly known as manganese nodules, are known to contain appreciable quantities of metals; for example, manganese, nickel, copper and cobalt⁶, that are of strategic significance to India. Nodules occur at water depths of 5 to 6 km in the Indian Ocean. Mining of these minerals

from the Indian Ocean would not only make India self-sufficient in strategic metals but also leave us with surplus metals (for instance, cobalt) for export. India's claim for an 'area' in the Indian Ocean was accepted by the United Nations and on 17 August, 1987, India became the first country in the world to get an area of 150,000 sq km allocated for resource development (Figure 3). As a part of our obligation to the UNCLOS-III, India identified yet another area of the same size in the Indian Ocean (Figure 3), for the International Seabed Authority, to exploit the nodule resources, in order to honour and fulfil the principle of the 'common heritage of mankind'. Later, countries such as Japan, the then USSR and France got their allocations in the Pacific Ocean. This achievement was entirely due to the sustained Indian efforts, especially the scientists from the NIO, since 1981. It would be apt to recall the statement made by the then Prime Minister, Rajiv Gandhi in the Parliament on 26 August, 1987, which is as follows⁷:

'The registration of our claim for a deep seabed mine site indeed provides a concrete indication of indigenous scientific capabilities and achievement. I am sure this House will agree to place on record our appreciation for excellent work done by our scientists and engineers who have taken up the challenging task for exploring new horizons of science to unravel the mysteries of the ocean.'

India has the trained manpower to harness seabed minerals lying at water depths of more than 5 km. Training programmes were organized for the UN personnel and India is developing the skilled manpower required for the International Seabed Authority. Our

research vessels were in the Indian Ocean until recently gathering more information on the exact nature of the seabed and viewing the resources with the help of deep-sea photography. This would lead us to earmark the 'areas' for mining in the near future. The Department of Ocean Development (DOD) is currently formulating long-range programmes on all the maritime zones, especially the legal Continental Shelf regime which needs to be demarcated by India, 10 years from the date of ratification of UNCLOS-III. It is estimated that about 1 million sq km additional area may be encompassed under the legal Continental Shelf of India once the demarcations are made. Further, emphasis is laid on the environmental impact assessment studies to understand the effects of future deep-sea bed mining on ocean dynamics and harmonious living of the biota in the deep-sea region of the Indian Ocean.

South Asia Cooperative Environment Programme (SACEP)

The SACEP formed under the aegis of the Marine Environment Programme of the UNEP to discuss and finalize a Regional Action Plan for the protection of the marine environment in the South Asian Seas Region. It became a legal entity on 7 January, 1982 when nine South Asian countries ratified the Articles of Association of SACEP. In a meeting attended by the plenipotentiaries of India, Bangladesh, Maldives, Pakistan and Sri Lanka, held in New Delhi, on March 24, 1995, the SACEP adopted an Action Plan and the DOD was designated as the Nodal Department⁸. The Action Plan specifies the priority activities including

- (a) Integrated Coastal Zone Management,
- (b) Development and implementation of national and regional oil and chemical spill contingency planning,
- (c) Human resource development through strengthening regional centres of excellence; and
- (d) Control of land-based sources of marine pollution.

In conclusion, the ratification and adoption of the Third UN Convention on the Law of the Sea by an overwhelming majority of nations, including India, and more so by the industrialized nations, established a new international order on the oceans. This should contribute to the sustainable use of oceans for the future good of nations, and to unravel the mysteries of mother nature. This marks a beginning for all nations to put concerted efforts and trust in the UN System, to solve problems related to harmonious living of mankind, and for peaceful use of the natural resources.

ACKNOWLEDGEMENTS. We thank Dr E. Desa, Director, for his initiative and enthusiasm to push this article for public readership. We sincerely thank the reviewing editor for his suggestions to improve the quality of this paper. We are indebted to the British Council, London for awarding fellowship to both of us for pursuing post-graduate studies and we owe a lot to the London School of Economics and Political Science, for the knowledge and formal education we have gained in Sea-use law, Economics and Policy-making. Our sincere thanks to the DOD for the financial support to many long-term projects at NIO, specially the 'Polymetallic Nodule Surveys' with which we are associated. The views expressed are those of the authors and may not necessarily reflect the views of the organization to which they belong.

Breeding for rice improvement: Where do we stand?

K. Muralidharan, G. S. V. Prasad and C. S. Rao

Rice dominates India's agricultural scene. Rice breeding programmes were started to improve yielding ability, increase efficiency in the use of external inputs and incorporate resistance to biotic and abiotic stresses.

INTRODUCTION of short-statured, non-lodging rice varieties in the mid-sixties led to the green revolution. In rainfed upland, rainfed shallow lowland, semideep water and deep water ecosystems, breeding for rice improvement was aimed at bettering yielding ability, or other traits like maturity duration, resistance to biotic and abiotic stresses or grain quality. From the breeding lines evaluated till 1994, 464 rice varieties have been released for cultivation in India. The grain yield performance data on check varieties and breeding stock, in various co-ordinated multilocal experiments were critically analysed to find the yield gains, if any, in the sequentially released varieties for each ecosystem. Within an ecosystem, there were no significant differences in most of the individual comparison of check variety mean grain yields. A few checks showed low variance and/or low CV, but the variances of the mean grain yields were homogenous. Only a few of these released varieties qualified as rational replacements for the earlier existing checks. Linear regression analyses were performed to find the yield improvement over years in the two floating checks – the mean grain yields of check varieties, both national and local, pooled over all locations tested; and the experimental mean grain yields calculated from yields recorded over all locations by breeding stock

evaluated. The two floating checks showed no yield gain in two decades of rice breeding. The successful incorporation of dwarfing gene in released varieties prevented lodging losses and improved yields harvested in indica rice. Later rice improvement efforts resulted in the diversification of genetic background, maturity duration, grain size and appearance, scent and quality, and incorporation of resistance to biotic and abiotic stresses in varieties released for various ecosystems. Compared to the first released semidwarf varieties in 1966–68, significant yield gain, through exploitation of hybrid vigour or development of new plant type, has not been demonstrated yet. Abandoning of breeding genotypes with similar yielding ability at most centres to fund new initiatives in raising the rice yields are discussed.

Rice dominates India's agricultural scene historically and geographically. Introduction of short statured and input responsive rice varieties during mid-sixties led to the green revolution. The areas under rice cultivation were grouped under five ecosystems: rainfed upland, rainfed shallow lowland, semideep water (< 50 cm depth), deep water (> 50 cm depth) and irrigated. Investments were then made in rice breeding programmes to generate varieties suited to these ecosystems. The aims were to improve yielding ability, increase efficiency in the use of external inputs and incorporate resistance to biotic and abiotic stresses. The multilocal tests of breeding stock developed at dif-

The authors are in the Directorate of Rice Research, Hyderabad 500 030, India.

ferent research centres were organized by the all-India co-ordinated rice improvement project¹. The evaluation of genotype \times environment interactions² in different ecosystems has been the rationale for the multidisciplinary approach to rice improvement research.

Depending on genotype sensitivity to photoperiod, three to four years are needed to identify a promising superior genotype on the basis of data from the multilocal tests³. In the first year, the newly evolved genotypes are tested in replicated local yield trials. The selected breeding lines from these experiments are included in the zonal co-ordinated trials called Initial Variety Trial (or Initial Evaluation Trial). Simultaneously, these breeding lines are also put to screening nursery tests for identifying their reaction to pests and diseases. The breeding lines that yield consistently well for two years are grouped to form Advanced Variety Trials (or Uniform Variety Trials) and tested for two more seasons. Agronomic data on these elite breeding lines are also generated during this period. After a careful scrutiny by different research centres, selected breeding lines are evaluated in on-farm trials for obtaining reaction of farmers and extension workers on the yield performance and acceptability. Considering yield records, agronomic data and the reaction to pests and diseases, candidate breeding lines are identified for release as varieties at the annual workshop by the co-ordinating unit. Each of these elite lines should have at least 10% stable superiority in yield or some special attribute such as disease or pest resistance or quality of the product endowing it with higher profitability or acceptance in the area recommended for its cultivation compared to the existing varieties of the area^{1,3}. A breeding line that fulfils these conditions is then named and released as a new 'high-yielding' variety to cultivators by the state or central variety release committee.

An appropriate comparison base is vital for the successful identification of higher yielding superior genotypes⁴. The traditional base is the standard check—usually a well known released variety that was found good for wide or local adaptability. Check varieties are commonly grown in plant breeding trials for a number of reasons: i) to provide a bench mark for evaluation of other lines⁵; ii) as a series of probe genotypes or interpretational cues to assist in the explanation of response patterns following the classification of all lines⁶; and iii) to aid in the prediction of the performance of new breeding lines in environments not under test, based on prior knowledge gained on the performance of checks in a wider range of environments⁶. In the dynamic rice breeding programme, once genotypes with improvement in yields or in other traits compared to checks are identified and released, some qualify for inclusion as checks. Therefore, a check variety has a variable but nevertheless short life span. The checks are updated frequently

so they do not remain the same over a long time. With each change in the check variety, there is a break in the constancy of comparison over time. In classifying genotypes based on data from plant breeding trials, the mean grain yields of both checks and experimental genotypes across environments are used as subjective choices.

During 1966–1994, up to 14,583 breeding lines have been evaluated nationally under the all India co-ordinated multidisciplinary and multilocal approach to rice improvement. Nearly 2139 elite lines have undergone four years of successful rigorous testing. This led to the identification and release of 464 varieties of rice, either by the states or by the centre⁷. A survey of the crosses developed in 30 breeding programmes showed that breeders gave maximum priority (>93%) to the objective of the improving yield potential⁸. Enhancement in grain yield over time is taken for granted as the target of >10% extra yields as compared to checks is fixed for selection of elite breeding lines for release as varieties and later for a replacement as checks. Over the years several released varieties have replaced the checks in all the ecosystems. The mean grain yields of checks, both national and local, across testing environments over years can be considered to represent a hypothetical floating check of Jensen⁴ that adjusts to yield gains, if any, with each replacement. The experimental mean yields derived from several genotypes across locations denote the base yield level of test breeding stock under different ecosystems and are comparable to another type floating check that adjusts to yields annually.

The aim of this study was to examine 1) whether the sequentially designated check varieties in the co-ordinated experiments were really selected on the basis of yield superiority and stability, and 2) whether there was any grain yield improvement in the two floating checks represented by the check mean grain yields and experimental mean grain yields. To address these objectives, the grain yield performance data on checks and breeding stock in various co-ordinated multilocal experiments under each ecosystem were critically analysed. The results may enable a better understanding on the credibility of the multilocal testing as well as on the benefits from such endeavours.

Materials and methods

Data sets on the performance of breeding lines and checks in 4719 all India co-ordinated experiments^{9,10} were used for this study. These experiments were performed between 1974 and 1994, at 53 locations in 16 states in India under direct-seeded rainfed upland, rainfed shallow lowland, semideep water, deep water and irrigated ecosystems during kharif (rainy) season. All

GENERAL ARTICLES

these experiments were conducted in randomized block designs with three replications. In rainfed upland experiments, seeds at the rate of 100 kg/ha were sown directly in lines. Every test breeding stock was line sown in 10 rows, each of which was 5 m in length. A spacing of 15 cm between rows or lines was adopted in all these experiments. This direct seeding was also adopted in semideep water and deep water ecosystems, at a spacing of 20 cm between rows and plants. In rainfed shallow lowland and irrigated ecosystems, 30-day-old seedlings were transplanted in experimental plots, at a spacing of 20 cm between rows and

15 cm between plants. The experimental plot size varied with locations; but in most cases the minimum plot size was 10 m². Efforts were made at all locations to ensure crop growth of test breeding stock by adjusting the time of direct seeding or planting, and fertilizer application to suit maturity period or ecosystem where a particular experiment was conducted. Fertilizer rates and insecticide applications were usually decided by the co-operator. In all treatment plots, one border row was excluded and grain from the remaining plants were harvested and expressed as t/ha at 14% moisture.

m = medium duration and me = mid-early duration.

Annada, Mahsuri, and Utkal Prabha are derivatives from *indica/japonica* crosses; Mahsuri was introduced from Malaysia. Jagannath is a mutant. Pranava is a derivative from *javanica/indica* cross. Pankaj and IR 36 were introduced from Philippines. Pankaj, Mahsuri, Jaya, Rasi and IR 36 have been released in many countries.

Data analysis

Details on the varieties used as checks in different ecosystems and the data sets used in this investigation are summarized in Table 1. For each check variety, the mean grain yield in the experiments across locations for each year was calculated. Ecosystem-wise, Bartlett's test of homogeneity of variances of mean grain yields in check varieties was applied¹¹. This is the most widely used and preferred measure as it is applicable whether each variance tested is dependent on the same or different numbers of degrees of freedom. In all possible combinations, comparisons of the mean grain yields¹² of check varieties were made. For each check variety, the coefficient of variation (CV%) in the mean grain yields was also estimated¹³. The CV of a cultivar across environments is considered¹⁴ as a biologically sound measure of its stability.

For each test year in different ecosystems, the mean grain yields for the two floating checks were estimated: 1) mean grain yields of checks, both national and local, were pooled over all locations tested; and 2) experimental mean grain yields were calculated from yields recorded over all locations by breeding stock evaluated. Linear regression analyses were performed to find the yield improvement over years in these two floating checks.

Performance of checks and breeding stock

Rainfed upland ecosystem

Comparisons were made among the mean grain yields recorded by the check varieties (Table 2) evaluated in 1367 experiments in rainfed uplands. Only Ratna exhibited significant differences in the mean grain yields in

comparison with Bala, which was the first released variety for commercial cultivation in rainfed uplands. Bala was denotified and withdrawn from cultivation in 1991 due to grain shattering and loss in harvest in farmers' fields. Ratna recorded highest mean grain yields (4.25 t/ha) under the direct-seeded conditions. The larger variance (0.172) recorded in Ratna was probably due to relatively high number of tests (431). The Bartlett's test showed that variances of mean grain yield of the check varieties were homogenous. Tulasi recorded the lowest variance (0.021) and CV (6.9%) indicating its stability.

During 1976–94, a total of 324 breeding stock was studied. The linear regressions of mean grain yields of the two floating checks in the experiments under rainfed upland ecosystem over time showed a significant decrease (Figure 1). The checks mean grain yields registered a significant decrease from 3.18 t/ha in 1976 to 2.44 t/ha in 1994 ($r = -0.56$). The experimental mean grain yields also registered a similar decrease from 3.22 t/ha in 1976 to 2.44 t/ha in 1994 ($r = -0.58$).

Rainfed shallow lowland ecosystem

Table 3 shows the comparisons made among the mean grain yields recorded by the check varieties evaluated in 760 experiments in rainfed shallow lowlands. Of the seven varieties used as checks, none exhibited any significant difference in the mean grain yields in comparison with Pankaj and Jagannath, which were the first released varieties for commercial cultivation in rainfed shallow lowlands. Jagannath showed sensitivity to photoperiod and was not found to be adapted to all rainfed areas. Therefore, Jagannath, was denotified and withdrawn from cultivation in 1991. Pranava and Salivahana recorded the highest yields. The Bartlett's test, however, showed that variances of mean grain yield of the check

the highest mean yields. The Bartlett's test showed that variances of mean grain yield of the check varieties were homogenous. Utkal Prabha, a derivative of *japonicalindica*, recorded the lowest variance (0.125) and CV (26%) indicating its stability; but the mean grain yield was lower than the other checks.

During 1979–94, a total of 306 breeding stock was studied. In the experiments under semideep water ecosystem, the linear regressions of mean grain yields of the two floating checks over time showed a non-significant increase (Figure 3). The checks mean grain yields remained nearly at 2.16 t/ha. The experimental mean grain yields also showed a non-significant increase from 1.73 t/ha in 1979 to 2.46 t/ha in 1994.

Deep water ecosystem

Comparisons were made among the mean grain yields recorded by the check varieties evaluated in 67 experiments in deep water ecosystem (Table 5). Of the three land races used as checks, none exhibited any significant difference in the mean grain yields in deep water ecosystem. Local cultivar recorded the highest mean yields. The Bartlett's test showed that variances of mean grain yield of the check varieties were homogenous. There were no significant differences either in the variances or in the yield performances. However, there were quantifiable differences in local cultivars over the other checks. Jalamagna recorded the lowest variance (0.169) and CV (22%) indicating its stability.

During 1984–94, a total of 138 breeding stock was studied in these experiments. The linear regressions of mean grain yields of the two floating checks in the experiments under deep water ecosystem over time showed a non-significant increase (Figure 4). The mean grain yields of both floating checks varied widely.

Figure 4. The performance of the two floating checks – check mean grain yields and experimental mean grain yields – across locations over time in the deep water ecosystem. Line fit represents the predicted mean grain yields.

Irrigated ecosystem

Comparisons were made among the mean grain yields recorded by the check varieties evaluated in 2268 experiments in irrigated ecosystem (Table 6). A mid-early

(125 days) and a medium (135 days) maturing local checks were included in these experiments. Only IR 36 and Rasi exhibited significant differences in the mean grain yields in comparison with Jaya, which was the first released variety for commercial cultivation in irrigated ecosystem. Both local checks and Jaya with medium maturity duration recorded the highest mean grain yields. The Bartlett's test showed that variances of mean grain yield of the check varieties were homogenous. Vikas with a mid-early maturity duration recorded the lowest variance (0.162) and CV (9.6%) indicating its stability.

During 1974–94, a total of 916 breeding stock (409 and 507, respectively, in 125 and 135 days maturity groups) was studied. The linear regressions of mean grain yields of the two floating checks in the experiments under irrigated ecosystem over time showed a highly significant positive increase (Figure 5). The checks mean grain yields registered an increase from 3.83 t/ha in 1974 to 4.74 t/ha in 1994 ($r = 0.66$). The experimental mean grain yields also registered an increase from 3.80 t/ha in 1974 to 4.68 t/ha in 1994 ($r = 0.72$).

Yield of breeding lines and varieties claimed as 'high-yielding'

Within an ecosystem, there were no significant differences in most of the individual comparisons of mean grain yields of check varieties. Only a few exceptions were observed. However, the Bartlett's test showed variances in mean grain yields of the check varieties in the different ecosystems to be homogenous. A few check varieties showed stability in grain yields with low variance and/or low CV. Only some of these released varieties qualified as replacements for the earlier existing checks: Akashi (1970), Annada (1987) and Tulasi

Figure 5. The performance of the two floating checks – check mean grain yields and experimental mean grain yields – across locations over time in the irrigated ecosystem. Line fit represents the predicted mean grain yields.

(1988) for rainfed upland ecosystem; Salivahana and Pranava (1988) for rainfed shallow lowland ecosystem; Utkal Prabha (1983) for semideep water ecosystem; and Vikas (1983, mid-early maturity duration) for irrigated ecosystem. No replacements were found for the checks, Jalamagna (1969) in deep water ecosystem and Jaya (1968, medium maturity duration) in irrigated ecosystem. The strategy of selecting for mean performance from a number of experiments at many locations has resulted in identification of varieties with wide eco-geographical adaptation. As a result of inclusion of one or two checks with good general adaptability, the national test becomes less sensitive for identifying a cultivar's specific adaptability¹⁴. Varieties meeting the criterion of low variance qualify to be named as stable genotypes but are not useful in a breeding programme for maximizing yields¹⁵. There was no consistent increase in the mean grain yields of varieties sequentially designated as checks in the trials for different ecosystems.

The two floating checks, namely, the checks mean grain yields and the experimental mean grain yields, showed no yield gain in two decades of rice breeding. In

fact, in the rainfed upland ecosystem, a significant decrease was discernible in the mean grain yield of these two floating checks. In other rainfed ecosystems, such as shallow lowland, semideep water and deep water ecosystems, there was no significant change in the yield levels, either in the check varieties or in the breeding stock tested over the years. A small but significant yield gain was obtained only in the irrigated ecosystem. This may be attributed to the improved crop husbandry skills and infrastructure development at the experimental locations over these years. In practice it is difficult to separate gains in yield potential in irrigated ecosystem, from the effects of interaction with increased plant density and higher doses of nitrogen. In terms of production gains in farmers' fields, advancement has been only in the non-fragile irrigated and in a part of rainfed ecosystems considered favourable¹⁶. Further, Jaya released in 1969 has remained unconquered for yield potential and continued to dominate as the highest yielding variety till date in the irrigated ecosystem.

In general, elite lines in all these experiments are promoted or discarded after comparisons with the two floating checks, the mean grain yields recorded by the checks and the experimental mean grain yields derived from the yields recorded by all the test lines. If the required condition of a >10% yield superiority¹⁷ in new variety over the previous check was realized in at least some selections, there would have been a consistent increase in mean grain yield in the new releases. If selection for yield in breeding programme has not been effective before inclusion of the newly bred lines in zonal or national trials, then it is not possible to obtain any yield gain at the later stages. Only information on their adaptation is what we achieved from the co-ordinated trials. The 10% numerical superiority claimed for breeding stock can come from either an under-estimation of the check variety or from an over-estimation of the new elite line. This probably led to a nomination of stereotyped breeding stock for evaluation in both national and state experiments. The four years' performance data often comes from a different set of locations, and combined analyses of locations and years are seldom presented when proposing an elite line for release.

Progress in rice breeding

Genotype \times environment interactions determine three major, genetically controlled, physiological components of yield such as the net accumulated biomass, harvest index and harvest maturity duration¹⁸. *Indica* rices are well known to produce high biomass. *Indica* cultivars such as Beria Bhonga produce sturdy culm with less number of tillers per plant. For variations in panicle weight and grain number per panicle also *indica*'s rec-

GENERAL ARTICLES

ord is unchallenged by 'high-yielding' varieties¹⁹. Traditional *indica* cultivars were, however, prone to lodging and consequent yield losses.

In many *indica* varieties, the overall loss as a result of lodging at pre-flowering stage was estimated at 60% of the grain yields¹⁹. Tall *indica* cultivars fail to express their yield potential in a community due to lodging and mutual shading²⁰. A removal of these inhibitions for estimating their yield potential through propping and wide spacing (50 × 50 cm) led to expression of high yields; with an extra dose of fertilizer (50 kg N/ha) application, the yields increased further. The single plant yields were higher in tall *indica* cultivars, such as Manoharsali (180 g), Handiquesali (180 g), Ngasein (155 g), and Ac 3289 (150 g)²⁰ than dwarf varieties, Jaya and Jagannath (120 g). By supporting tall varieties including *indica* variety, Mtu 15, with bamboo sticks, Jennings at the International Rice Research Institute, Philippines, found that tall varieties yielded essentially as well as did lodging resistant varieties. Moreover the lodging-susceptible varieties when supported, responded well to nitrogen application whereas unsupported plants showed a decided negative response to nitrogenous fertilizers²¹. By the identification and introduction of *DGWG* gene into varieties, non-lodging dwarf stature was achieved with an improvement only in yields harvested. Compared to *indica* land races, the harvest index increased along with a reduction in plant height in the first 'high-yielding' varieties TN 1 and IR 8. Realizing the value of straw in cattle rich rice growing areas, later selections resulted in semidwarf or semitall varieties where aerial biomass was increased. In these semidwarfs, although the harvest index reduced, relatively the maximum grain yields obtained were comparable to the *indicas* and first dwarfs.

The new varieties developed for the different rice ecosystems in the post-green revolution phase have not provided any genetic gains in yield. Exploiting the advantage of multilocal experiments spanning three decades, a number of varieties were released with similar yield potential. However, they differed in other attributes. Varieties with varying maturity duration (early, mid-early, medium, and late) were also developed. In these released varieties, maturity duration, grain size, appearance, scent and quality, resistance to biotic and abiotic stresses could be tailored to suit consumer preferences and needs^{22,23}. Therefore, they replaced the traditional cultivars and the varieties released during the green revolution phase. The periodic release of other cultivars after 1980 resulted in yield stability, at the cost of a marginal reduction in yields. For the different ecosystems, breeding efforts have led to the development of a number of varieties derived from genetically diverse parents but with similar yielding ability. The remarkable diversity attained in rice varieties can be illustrated with

Figure 6. Phalguna – a hitherto resistant variety suddenly showed susceptibility to gall midge (*Orseolia oryzae*) in 1986, after a decade under cultivation in farmers' fields in north coastal Andhra Pradesh. Rice breeding lines developed using diverse genetic sources before a prior knowledge on this new biotype, were tested at Srikakulam district, Andhra Pradesh in 1987. A few elite genotypes from each of the three breeding centres, Directorate of Rice Research, Indira Gandhi Krishi Vishwa Vidyalaya and Central Rice Research Institute, showed resistance like IET 10300 to this new gall midge biotype while Phalguna succumbed²⁴. This remarkable diversity achieved in rice genotypes warrants a reconsideration on maintenance breeding aimed at developing resistant varieties.

the quick success in releasing a variety resistant to a newly-discovered gall midge biotype²⁴. A test of breeding lines developed before a knowledge on this biotype in the area where this new biotype outbreak was observed enabled identification of resistance (Figure 6). Therefore, maintenance research aimed at retaining the levels of resistance considered critical to yield stability^{8,23} is no longer needed in rice improvement programmes¹⁶.

In many crop species, check varieties are normally considered to suffer time erosion as higher yield levels are reached through a genetic yield gain in new breeding lines²⁵. But in this study, results obtained on the performance of checks over time show no evidence of time erosion as there has been no genetic gain in rice varieties developed for specific ecosystems. In each of the ecosystems studied, the checks showed similar yield levels, suggesting that there was redundancy in their replacement. Both national and state rice research centres face critical budgetary shortages. Most breeding programmes operate under tight financial constraints. This demands a rationalization of the size, number and location of rice breeding programmes aimed at generating breeding stock with similar yielding ability. Therefore, abandoning such programmes at most centres would free a substantial resource that could be used in searching for the elusive yield gain.

Avenues for increasing yield

Yield improvement in the successively released varieties of crop species do not show a linear increase²⁵. Rather, the increases have come as steps or a series of small plateau. A yield plateau may exist momentarily, for a certain species in a given region. Usually, each yield improvement to a new small plateau can be associated with the exploitation of a new source of germplasm or trait. Early success of the rice and wheat breeding programme is the result of the definition of a strategy. To ensure maximum progress in a relatively short time, work was concentrated in high-yielding environments defined by irrigation and fertilizer usage. The selection was made for high harvest index types characterized by short stem, erect leaves and photoperiod insensitivity^{26,27}. No yield gains have arisen from selecting for net photosynthesis, nitrogen fixation and utilization, photo- and dark-respiration, light interception, leaf chlorophyll content and enzymes in the pathways of photosynthesis and nitrogen fertilization. Selection for physiological traits will fail to assist breeding for higher yield if their gene actions occur before the actual accumulation of the yield. Wallace and colleagues suggested that failure occurs because the gene activities interact with too many other segregating gene effects. Further, in the physiological processes, the numerous interconnections among parts of the system cause their genetic influence to become unpredictable¹⁸.

Widespread use of single cross corn hybrids after 1960 resulted in a yield jump²⁵. Successful exploitation of hybrid vigour in harvesting higher farm yields in rice has been reported only in China so far. The hybrid rice seed is relatively costly. The induction of male sterility in plants by a dominant chimeric ribonuclease gene²⁸ has demonstrated the possibility of reducing the seed cost. But the yield advantage of hybrids released so far over conventional is a modest 15% (ref. 29). The yield potential of 10 t/ha established by IR 8 and Jaya, the first released semidwarfs²², has not been surpassed so far. In developing high-yielding rice varieties for different ecosystems, the need for a radical change has already been recognized³⁰. Breeding new plant types was initiated during 1989 at the International Rice Research Institute, Philippines, for pushing the yields further. The new plant type with short stature, sturdy stem, panicles with large number of grains (150–200), reduced tillering (5–10 tillers), and erect dark green and thick leaves were developed using the tropical *japonica* germplasm. During the 1994 dry season, 14-day-old seedlings of these elite lines were transplanted at one seedling/hill at different plant densities and fertilized with 200 kg N/ha applied in five split applications. Despite this intensive management, the yields recorded in new plant type advanced breeding lines were not significantly different from the check variety, IR 72 (ref. 31).

In the quest for higher yields, breeding for morphological traits to improve the yielding capabilities of future varieties is appropriate. Valuable yield genes do exist in remote and often unexpected plant materials and successful use of germplasm for improvement of yield could be made. This scope for yield gains by bringing together germplasm from very exotic (completely non-homologous) sources have been demonstrated by the development of triticales³². During 1970–85, research efforts led to realization of increases in total biomass and grains per tiller in wheat. As a result a dramatic increase of 10–20% in grain filling rates occurred in selected lines of *Triticum aestivum*. The reason for this increase is attributed to 1B/1R wheat/rye-derived translocation³³.

Rice germplasm has a rich diversity for the number of panicles per plant, panicle weight, and grain size. Genotypes with over 350 grains per panicle as in Kolomba rices³⁴ such as K 540 and EK 70, or with a test weight of 4.8 g per 100 grains in T 930 from Bengal collection³⁵, have been identified. Grain yield improvements have already been reported in *Triticum durum* from the increased grain number per spikelet³⁶. Most of these traits are supposed to be polygenically controlled. Quantitative genetic models give an insight into the genetic control of a trait. Highly saturated molecular marker linkage maps are available in rice^{37,38}. However, their practical application is still warranted. It is now possible to use these maps to establish associations between marker alleles and genes controlling yield traits. This will enormously decrease the time involved in evaluation. Molecular markers go further, permitting not only determination of the number of chromosomal segments controlling a quantitative trait but also their location on a given chromosome with relative precision. The improved breeding efficiency will be sustained only when aided by good breeding population and their efficient management. New tools are available to the rice breeders for the introduction of specific yield contributing genes into a new plant type. Traits governed by single or a few genes are likely to be inserted successfully. Therefore, new initiatives are needed to identify the required genes in germplasm and deploy such genes in future varieties using skills and modern tools available today for achieving a genetic gain in rice yields.

ACKNOWLEDGEMENTS. We thank the scientists responsible for conducting the all India co-ordinated rice experiments at different centres in various years. We thank Dr R. S. Paroda (DARE & ICAR) for suggesting a critical review analysis of yield in rice varieties. We thank Dr E. A. Siddiq (ICAR) and Dr K. Krishnaiah (DRR) for extending facilities to take up this study. We are also grateful to Dr S. V. S. Shastry and T. E. Srinivasan (AICRIP) for encouragement and guidance in our investigation. We thank Dr M. V. Rao (Andhra Pradesh Agricultural University), and Dr N. G. P. Rao (ASRB, ICAR) for a critical review and for valuable suggestions. The support from World Bank (National Agricultural Research Project on IPM in Rice) is gratefully acknowledged.

PCR-based detection of *Listeria monocytogenes* in dairy foods

S. K. Sood and Jasjit Kaur*

Embryo Biotechnology Centre and *Division of Dairy Cattle Nutrition, National Dairy Research Institute, Karnal 132 001, India

Consumption of dairy foods has been recognized as an important transmission route for human listeriosis, causing health hazards among public. This demands a successful detection assay to declare dairy foods free of *Listeria monocytogenes*, the causative pathogen. Although PCR-based detection of *L. monocytogenes* in dairy foods is associated with problems of PCR inhibition and carry-over contamination, PCR have been applied widely for successful detection of *L. monocytogenes* in dairy foods and found useful for suggesting, monitoring and control measures. Therefore, in the present report, PCR-based detection protocols with special reference to overcome PCR inhibition by dairy foods and culture media constituents over the last 5 years are discussed. Also, critical tips to be kept in mind while performing PCR-based *L. monocytogenes* detection assay are enumerated.

CONSUMPTION of safe food has always been the desire of man. It has now acquired commercial importance with more and more people consuming prepacked food and dairy products. Consequently, the detection of pathogens became cardinal in any centralized food preparation. Although *Listeria monocytogenes* has been recognized as a cause of disease in humans and animals for over 50 years, recognition of listeriosis as an important public health problem dates from the documentation of common source food-borne outbreaks in the last decade¹⁻¹¹ with special risk groups of pregnant women, newborns, elderly and immuno-compromised patients (Figure 1).

Listeria monocytogenes (Table 1) is a human and animal pathogen which is widespread in nature. It is a transient constituent of the intestinal flora excreted by 1-10% of healthy humans. It is extremely hardy and can survive for many years in the cold in naturally infected sources. *L. monocytogenes* has been isolated from a wide variety of foods, including dairy, meat and fish. Most of the food-borne listeriosis outbreaks have been linked to the consumption of dairy foods. Also the evidence that gastrointestinal tract is an important route of infection and that the epithelial cells of the intestine may be primary site of entry for these bacteria has been provided by electron microscopic studies of tissues of in-

fectured guinea pigs¹². It is now recognized that listeriolysin O, a 60-kDa protein, is one of the major virulence factors of the organism. All strains of *L. monocytogenes* are pathogenic by definition although some appear to be more virulent than others.

Besides the above epidemics, *L. monocytogenes* have also been found in dairy foods spanning other parts of the world, viz. Egypt¹³, Singapore¹⁴, United Arab Emirates¹⁵, Scotland¹⁶, Spain¹⁷, Ethiopia¹⁸, Jordan¹⁹, Taiwan²⁰, Italy²¹, Tokyo²², France²³, Poland^{24,25}, Brazil²⁶, New Zealand²⁷, China²⁸, Denmark¹¹, and England and Wales²⁹. The presence of *L. monocytogenes* in dairy foods is mainly due to contamination of raw milk, survival following improper pasteurization, post-pasteurization contamination, resistance to production technologies, contamination during cheese ripening, and survival and growth during product storage³⁰. Therefore, whether the dairy foods are manufactured from raw milk or pasteurized milk, strict detection for *L. monocytogenes* is required to be undertaken.

There is no study available on the incidence of *L. monocytogenes* in India. Since the dairy processing industry in India is growing rapidly as was in the developed world before epidemics, the possibility of such epidemics in India, therefore, cannot be ruled out completely. Consequently, methods for detection of dairy foods-borne *L. monocytogenes* are required for protecting the health of public. Further, questions regarding the epidemiology of the disease, the extent of dairy foods contamination and the importance of the foodborne route of transmission remain unanswered partly due to lack of successful detection assay. A successful assay must be simple, sensitive, specific, reliable, accurate and above all rapid, for detection and identification of *L. monocytogenes* so as to warn against the use of contaminated dairy foods (which have limited shelf life) well in advance. Since an oral infective dose of 10⁵ virulent *L. monocytogenes* is required to cross the intestinal barrier in healthy immunocompetent humans, future studies aiming to determine the potential hazard of *L. monocytogenes* in foods should focus on quantitative rather than qualitative bacteriological aspects³¹.

Various approaches, viz. classical culture, ELISA, DNA probing, miniaturized biochemical assays, etc.

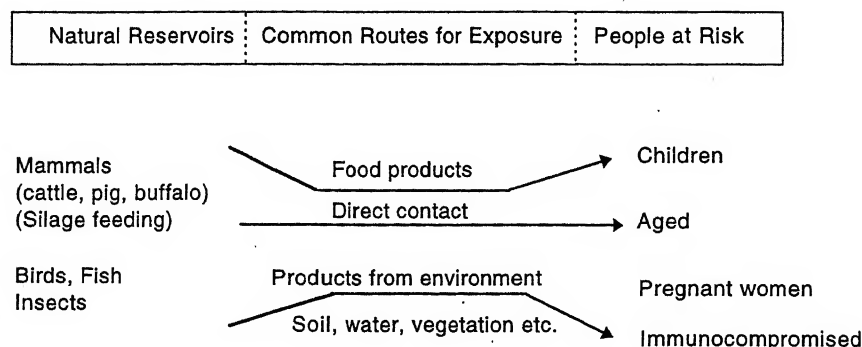

Figure 1. Natural reservoirs, common routes for exposure and people at risk of *L. monocytogenes*.

Table 1. General description of *L. monocytogenes*

Character	Description
General	Rod shaped, 2*0.5 µM, Non spore former, Gram +ve
Motility	Tumbling
Habitat	Soil, vegetation, sewage, silage, water and food
Route of infection	Food and water
Virulence factors	60 kDa, 49 kDa, 40 kDa and 34 kDa
Antibiotic sensitivity	Ampicillin, chloramphenicol, erythromycin, neomycin, tetracycline, cephalosporin

have been used to detect *L. monocytogenes*. The ELISA assay was able to detect *Listeria innocua*, *L. monocytogenes*, *L. murrayi* and *L. welshimeri* after 48 h in artificially contaminated cheese with high sensitivity but without specificity³². A hydrophobic grid-membrane filter (HGMF) colony hybridization method using a digoxigenin-labelled DNA probe is potentially useful for automated detection of the organisms in foods³³. No interference with the present background flora was noticed in a DNA probe assay with the colonies, grown on the selective agar plate, swabbed and washed prior to analysis³⁴.

Approaches used in the past lack one or other criteria of successful detection assay. Standard methods which rely on cultivation of presumptive *Listeria* colonies is time consuming taking 3 to 4 weeks before a species identification is possible³⁵. Therefore, by the time results are available, the product is already consumed. Identification of *L. monocytogenes* by colony hybridization with a specific DNA probe has been reported^{36,37} but here also prior cultivation of the organisms was necessary. A sensitive, quantitative hybridization assay using riboprobes against *Listeria* 16S rRNA has been described³⁸, although the specificity for *L. monocytogenes* was not reported.

The development of primer-directed enzymatic amplification of DNA with a thermostable DNA polymerase, i.e. polymerase chain reaction (PCR)³⁹ and its application to amplify specific fragments of bacterial DNA precede a detection assay which meets all the criteria for successful detection, identification and confirmation of *L. monocytogenes*. Sensitivity of the PCR method for cheese wash-water was higher than classical and the DNA colony-hybridization method⁴⁰. PCR applied to a 2-step enrichment was the most powerful assay for detecting *L. monocytogenes* among selective agar plating, by 'Gen-Probe' DNA hybridization and by the polymerase chain reaction (PCR)⁴¹. With the widespread studies on *L. monocytogenes* in dairy foods, a number of research reports have accumulated over the past 5 years describing various protocols and experimental modifications for its detection.

PCR-based detection assay

PCR in an *in vitro* method for amplification of specific DNA fragments (Figure 2). Two oligonucleotide primers, each complementary to the extremes of opposite strands of DNA separated by a region to be amplified, direct the synthesis of a complementary strand towards each other to produce an exact copy of DNA flanked by primers. Repeating the cycle of 3 independent steps carried out at defined temperatures doubles the numbers, thus increasing the copy number of target DNA in a geometrical fashion (approximately $m2^n$). Here m is the initial copy number of target DNA and n is the number of PCR cycles. The steps involved are denaturation (94–97°C), primer annealing (55–72°C) and extension of annealed primers (at about 72°C) by a thermostable DNA polymerase.

Detection of foodborne microbial pathogens using PCR has been applied widely and reviewed^{42,43}. Denner and Boychuk⁴⁴ developed a species-specific

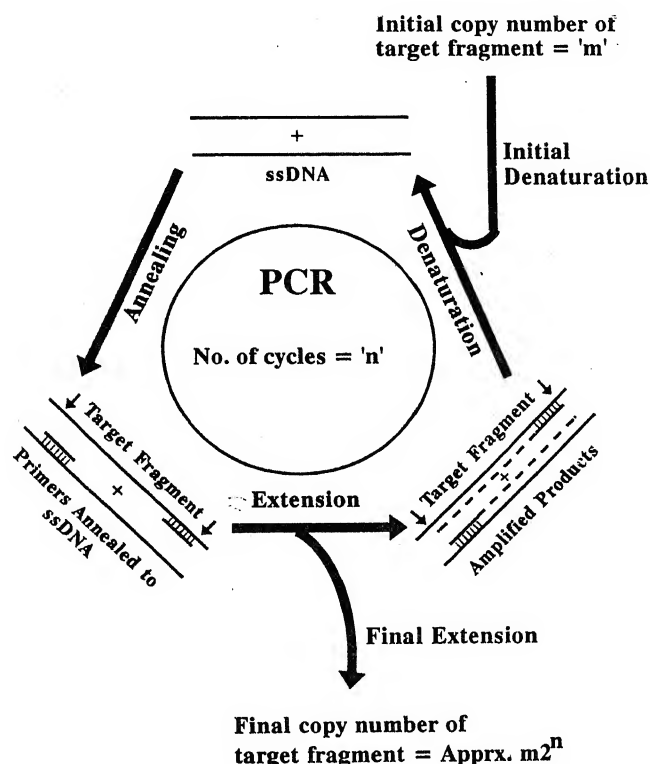

Figure 2. Diagrammatic representation of PCR.

detection assay of *L. monocytogenes* by DNA amplification. Niederhauser and his associates⁴⁵ detected *L. monocytogenes* in food using a PCR-based assay. Since then, a number of research reports have accumulated describing various protocols and experimental modifications for detection of *L. monocytogenes* dairy foods.

In comparison to other methods, PCR offers the following advantages as summarized⁴⁶: (i) a short time requirement improves public health security and minimizes personnel costs; (ii) the method is able to identify microorganisms that are difficult to culture; (iii) the culture and enrichment of pathogens are not necessary for quality control; (iv) PCR reagents are more readily available and easier to store than those required for serological procedures; (v) animal models are not needed; (vi) the choice of primers determines specificity, which contrasts with the fragment cross-reactivities of antisera utilized in immunoassays; (vi) elaborate diagnostic equipment and media are not required, thereby increasing the flexibility as to locations where PCR may be performed and (vii) automated thermocyclers are available.

Principle of the detection assay

Small portion from the sample dairy food is taken for investigation (Figure 3). PCR with *L. monocytogenes*
